Abstract

In the article, the authors made an attempt to confront the prevailing in the scientific debate view on the shape and functions of the so-called smart urban space, or Smart CITY, with experiences resulting – especially for city residents and management – from the Covid-19 pandemic. After a short introduction, the initial part of the article briefly presents the current shape of the Smart City concept, treated in terms of a paradigm (proposed by Kuhn). Based on such an SC paradigm, the next part of the article presents an outline of the methodology and an attempt to identify areas that fall within the above paradigm, that has been most frequently undertaken in research to date and most often described in available publications. Then, an overview of the problems of an SC – undervalued, according to the authors of the article, in the research carried out so far – is presented. The next part of the article presents the results of extensive surveys of Polish cities on the implementation of the Smart City paradigm. The surveys were conducted in the period immediately preceding the pandemic. After analysing the results of these studies, an attempt was made to determine the level of openness to new challenges in the thinking of city management to new problems and challenges, "absent" in the current paradigm. The final part of the article presents the proprietary list of new needs of a Smart City and its stakeholders, identified as a result of the pandemic experience, as well as the proprietary list of new solutions and a rough analysis of the possibilities of their implementation in the areas of "smart cities".

Keywords: Smart City, Covid-19 pandemic.

Introduction

From the moment when craftsmanship, as an area of producing goods, entered into an alliance with science, understood as a source of not only abstract and cognitive knowledge, but also utilitarian, offering means and methods of production, societies of the following centuries benefited from such an alliance. From the age of industrial-scale steam, coal and steel production, to the age of wide-scale use of electricity, and then to the automation of production processes, we, as a society, have come to the point where the modern economy is based on knowledge. The age of steam and electricity required newer and more technologically advanced sources of energy to power factories and industrial installations. In view of the increasing availability and decreasing cost intensity, the usage of energy has also extended to places used by all of the society, not related to production, such as homes and housing estates, social infrastructure (hospitals, schools and other similar institutions), public transport and others.

Another breakthrough in the economic development was knowledge-based economy, which also forced the rapid development of supplying such an economy with the necessary "fuel", which is broadly understood information. We have learned to obtain, collect, process and share such information on a previously unprecedented scale. Again, the growing supply made it possible to use information resources to satisfy social needs in the above-mentioned non-productive areas. A special place in these areas is occupied by the space where people live, especially in urbanised areas.

In recent years, many scientific communities have conducted – and continue to conduct – multi-topic discussions on the directions, rules and basic conditions for the development of urbanised space in the conditions of the growing supply of information and tools for using such information for the needs of city residents or – more broadly – urbanised areas. The key concept in this discussion is the concept of a "Smart City" (SC).

Bearing in mind the function of smart cities in creating technological progress and enhancing the development of civilisation, the authors of this article decided to identify the main directions of transformations and the functioning of smart cities, resulting from the experiences of the Covid-19 pandemic. For this purpose, they used a review of previous publications on Smart Cities, the results of their own research documenting the practical interest in the implementation of this concept by municipal authorities in Poland and observations of city life over the last several months. Conclusions resulting from the considerations are a contribution to in-depth research and detailed analyses on the impact of health threats on the development of smart cities and the prioritisation of their development priorities.

Literature Studies

Subjective representation of the "Smart City" paradigm

The concept of a "Smart City" (SC) can be considered as a specific development of the previously formulated idea of a "digital city" (van Bastelaer and Lobet-Maris, 1998; Ishida, 2000; Partridge et al., 2005; Hollands, 2008), "creative city" (Hall, 2000), "knowledge city" (Carrillo, 2006) or "intelligent city" (Komninos, 2009), which appeared in publications from the last decade of the 20th century. Proposing the Smart City model (and concept), related to the similarity of digital/smart urban space elements to human sensory/nervous system components, most often dates back to 2007 and is usually attributed to the research team from the Massachusetts Institute of Technology, although the idea for (and even the term) "Smart City" appears in studies from a similar period, coming from other research centres (Coe, Paquet and Roy, 2001), (Bertinelli and Black, 2004), (Lindskog, 2004), (Carrillo, 2006), (Hollands, 2008), (Giffinger, Haindlmaier and Kramar, 2010).

In the rich – despite the relatively short time that has passed since the publication of the initial studies – literature on the subject, we encounter general considerations, for example, looking for an answer to the question whether a "smart city" is another utopia (Mora and Deakin, 2019) or looking for references to political trends, such as neoliberalism (Storper, 2016). In research on smart urban space, references are also made to research related to "classic" areas of science, such as architecture and urban planning, construction, urban engineering, applied computer science, logistics and transport, or environmental engineering. On the other hand, in publications containing in the title a reference to a smart urbanised space, juxtaposed with the presence of its residents (or – more generally – users) in this space, there are many references to "soft" sciences, such as sociology, psychology or management and quality sciences.

Previous research has shaped a certain paradigm of a Smart City, as in the view introduced by Thomas Kuhn in the book The Structure of Scientific Revolutions (De Guimarães et al., 2020). According to this view, a paradigm is a set of concepts and theories that form the basis of a given science. The "Smart City" paradigm, in its current shape, results from the experience and research results, especially on the shape of urban space (architectural and urban approach), on its information and IT infrastructure (ICT approach (Beltrán-Ramírez et al., 2015), on technical and logistical infrastructure (transport systems, media management: energy, water and sewage, waste management), on the behaviour of residents and groups of city residents (sociological and psychological approach), and on other groups of problems essential for the functioning of urban spaces.

Among the authors of studies on Smart Cities, there was also – and still is – a lively discussion on whether – for example – for the shape of smart urban space, the most important thing is to take into account the concept of Sustainability (Sampria et al., 2016), implement solutions in the field of Green and/or Reverse Economy, or maybe the participation of the "last mile" stakeholders, i.e. city residents, in shaping its "smart-ness" in accordance with the participatory approach? The authors of this study believe that previous work has failed to attempt to prioritise the tasks carried out by smart urban space. Certainly, one should – firstly – ask what would become the basis for such a "hierarchisation of needs". Another obvious question is the question of the advisability of such a hierarchy. And – last but not least – the question of the authorship (source?) of the proposed Smart City task hierarchy.

Establishing a ranking of the directions of increasing the "smart level" of a given urban space may be related, for example, to the identification of decision-makers. In an interesting study (Engelbert, van Zoonen and Hirzalla, 2019), the authors refer to a situation, in which projects related to the creation of smart urban space are submitted for co-financing from EU funds. The authors of such projects (as a rule: city/local decision-makers) are, on the one hand, guided by their own conviction, and on the other – by their assumptions about not whether the substantive area of the project is a real priority for the residents of a given area, but whether it has a reasonable chance in the assessment of experts representing the potential donor.

However, the experience of recent months shows, that the deep conviction of decision-makers about their own rightness, and even a solid initial recognition of the residents' expectations, may not be a sufficient premise for

decisions in the discussed area. Let us consider to what extent the previously accepted Smart City paradigm will prove successful in a situation, where it turns out that sudden and unexpected, and – at the same time – extremely important premises turned the hierarchy of needs "upside down" in Smart City projects.

The authors of this study intend to discuss the following thesis: the present shape of the Smart City paradigm must be at least expanded, if not completely rebuilt, in connection with the experiences of urban communities resulting from the current Covid-19 pandemic. For example, it is worth asking the question: have the current leaders of Smart City rankings proved to be the most effective in fighting the pandemic with urban organisms?

In the next part of this study, an attempt was made to conduct a targeted review of previous research in search of task areas that were somewhat "neglected" by scientists active in Smart City research and by decision-makers implementing specific solutions, which may be of key importance for smart cities in the "post-pandemic" period. Such areas can be identified not only by reading available publications. A dozen or so months ago, the authors of this study were on a working visit to a significant university, located in one of the largest countries of the European Union. The aim of the talks conducted during this visit was to get to know each other's general approach to Smart City issues, as well as the research and implementation works carried out. One of our partner's colleagues, a doctor, also participated in the talks, but the content of the discussion showed that other participants of the talks were not entirely convinced that the issues of broadly understood health care are included in the considerations regarding Smart Cities. One can jokingly say here that, if a Smart City is a city offering a high level of quality of life to young, happy, environmentally-conscious and physically active people, then – in order not to disrupt such an ideal image – poor health should be the basis for relegating someone from smart urban space.

It was assumed, that the starting point for the intended exploration will be the identification of problem areas related to the Smart City paradigm, most often described in the available literature. The methodology of such explorations is described in the next part of this study. On the other hand, the authors decided to create a list of such areas, that have not been appreciated by researchers and decision-makers so far, and from the perspective of the pandemic experience, they should be very high on the list of criteria for assessing whether, in 2020 (and in later years), a given urban space can actually be considered "smart".

Problem areas undervalued in previous research on Smart Cities Subjective representation of the "Smart City" paradigm

The term "smart city" appeared in literature and economic practice in the last decade of the twentieth century, along with the intensive development of information and communication technologies, and was initially defined and interpreted mainly in the context of their use and development in urban infrastructure (Kumar et al., 2019; Hui et al., 2017). However, with time, it began to be noticed that such an understanding of a smart city mainly serves the suppliers of solutions from the IT and ICT sector, who treat the city as an attractive market, and the products and services they sell are not always a response to the needs of municipal authorities and residents (Lom and Pribyl, 2020; Šurdonja et al., 2020; Barba-Sánchez et al., 2019; Kummitha, 2019; Albino, 2015; Jucevičius et al., 2014). It was an impulse to redefine the notion and concept of a smart city.

In the new terminology version, representatives of the urban community began to be included in the process of planning, creating and developing intelligent solutions (Chamoso et al., 2020; Simonofski et al., 2019; Moustaka et al., 2019). This made it possible to humanise the understanding of a smart city and supplement it with a social aspect. As a result, the implementation of modern urban technologies was focused on meeting the needs of residents and improving the quality of their life in the city (Yigitcanlar et al., 2019; Chen et al., 2017; McNeill, 2015; Moser, 2015; Castells, 1996).

The progressive degradation of the natural environment, especially intense in the last decade, and the popularisation of the concept of sustainable development, resulted in the further evolution of the notion and concept of a smart city. In addition to technological, economic and social aspects, the definition of a smart city also includes issues related to environmental protection and ecological education (Sepasgozar et al., 2019; Yu et al., 2019). In this way, a smart city has also become a sustainable city (De Guimarães et al., 2020; Mattoni et al., 2019; Patel and Doshi, 2019; Kobza and Hermanowicz, 2018; Ahvenniemi et al., 2017).

The systematic increase in interest in research in the field of smart cities in the period when this concept was constituted is perfectly illustrated by the growing number of research articles devoted to this issue published in one of the world's largest publishing houses – Elsevier (Fig. 1). In 2012, their number exceeded 1,000, and over the next 7 years it increased almost fivefold.

Fig. 1: Number of research articles devoted to the topic of Smart Cities and published in journals of the Elsevier publishing house in 1996-2020* (in 2020 – until April). Source: own study based on the Elsevier database.

Despite the development of research on the essence and functioning of smart cities, issues related to the development of urban information, telecommunications and energy systems still dominate among the publications mentioned. Much less attention is paid to ecological and social aspects (Table 1).

Table 1: A list of ten journals from the Elsevier publishing house with the largest number of articles devoted to the topic of Smart Cities in 1996-2020

No.	Journal title	Number of articles	The main areas covered by the journal
1.	Procedia Computer Science	775	computer science, mathematics, telecommunications
2.	Journal of Cleaner Production	745	environmental engineering, transport, materials science
3.	Energy Procedia	695	energy, environmental engineering
4.	Future Generation Computer Systems	636	computer science, mathematics, telecommunications
5.	Sustainable Cities and Society	576	architecture and urban planning, spatial management, environmental protection, sociology, management
6.	Applied Energy	554	energy, automatics, electronics, electrical engineering
7.	Energy Policy	550	energy, architecture and urban planning, environmental engineering
8.	Procedia - Social and Behavioral Sciences	536	sociology, psychology, pedagogy, management, economics, finance

9.	Energy	517	energy, architecture and urban planning, environmental engineering
10.	Energy and Buildings	454	energy, architecture and urban planning, environmental engineering

Source: own study based on the Elsevier database.

The issues related to the health condition of the residents of smart cities are discussed even less frequently than social or environmental issues. An extensive literature review, carried out by Portuguese scientists in 2019, indicates (Rocha et al., 2019) that, out of 8,130 articles from the Web of Science and Scopus database, referring to the topic Smart Health or Public Health in Smart Cities, only 19 were devoted to disease prevention, development of health care in cities or health promotion, i.e. public health. Most of the publications concerned a healthy lifestyle, including its aspects, such as tourism, mobility, sports activity or a healthy diet. Therefore, the authors primarily focused on improving the quality of life (Trencher and Karvonen, 2017; Casino et al., 2017), adopting the idealistic assumption of full risk control and a high standard of health care in smart cities. Issues related to diseases, health problems, potential threats to the health and life of residents and the functioning of the health care system have been marginalised. This approach can be considered – according to the authors of this study – as ignoring difficult and inconvenient topics, such as: illness, old age, disability or exclusion. Such an assessment is additionally confirmed by the fact that, among the 19 mentioned publications, only two concerned the living conditions of the elderly (Paolini et al., 2017; Urosevic et al., 2017), and two were devoted to epidemic threats (Patsakis et al., 2014; Beltrán-Ramírez et al., 2015).

Few authors also decide to describe early warning systems against health threats in smart cities, although the simplest of them, based on the analysis of data available on the Internet, are easy and practically cost-free to use and interpret. An example of such a solution is Google Trends, which can be successfully used to integrate network traffic data and, on this basis, identify areas of individual health threats and needs for the development of health systems in smart cities (Sampria et al., 2016).

However, It is worth adding that descriptions of smart pro-health solutions appear quite often in practice and literature in the field of smart cities in the ICT context, including that related to the Internet of Things (Zhang et al., 2018; Mshali et al., 2018). They are used to monitor the health of people with chronic diseases and take the form of applications or devices (Sicari et al., 2017; Chatrati et al., 2020). Such solutions have been adopted for the purposes of fighting the coronavirus epidemic to identify the whereabouts of people who are periodically quarantined or infected with Covid-19, but treated at home or in isolation.

The described view of smart cities proves their utopian perception, in which the priority is the continuous improvement of the quality of life of residents, but mainly of those who have already achieved a very high standard of living in terms of civilisation, economy, health and society. As a result, a smart city becomes a space where there is no room for unpleasant, complicated existential problems, that obviously cannot be eliminated. The consequences of such an approach and ignoring health threats are very serious, as confirmed by the coronavirus pandemic, which is most severely experienced by smart cities, which are the centres of largest populations of humans.

Methodology

Three research perspectives were used to identify patterns and consequences of the transformation of mining regions and cities. The first of these relates to the national level (Poland) and the three main mining basins: Lubelskie, Górnośląskie and Dolnośląskie. The second concerns the region, which is the Śląskie Province - the area of operation of the Górnośląskie Coal Basin, and the third is local and covers 19 Śląsk cities with poviat rights. This approach allows one to look at the process of changes and their consequences both synthetically and analytically.
The research is looking for answers to the following research problems:

1. At what stage is hard coal mining in three main mining regions in Poland?
2. What mining regions transformation paths have been implemented in each of the studied regions?
3. Were the cities located in the same mining region transformed in a similar or different way?
4. What influenced possible differences in urban transformation paths and their consequences?
5. What were the socio-economic consequences of selected transformation paths at regional and local level?

The analysis covered a 15-year research period - 2003-2017. In the course of the research, the following parameters were used to identify the socio-economic consequences of the transformation of regions and cities: population, budget revenues per capita, budget expenditure per capita, divided into current and investment expenditure, level of budget deficit/surplus, relation of total liabilities to total income.

For the data characterising the above parameters in the years 2003-2017, the average annual rate of change and arithmetic means were calculated, and based on them, a comparative analysis was carried out in the above mentioned research perspectives. At the end of the article, in order to group the 19 studied cities and formulate uniform management recommendations for them, Principal Components Analysis (PCA) was used to simplify the description of the studied cities from five parameters to two dimensions (Statistica Package), thus obtaining a description of the socio-economic consequences caused by choosing a specific transformation path.

A subjective and detailed analysis of the literature allowed to identify an important and current research gap in the area of research and analysis regarding Smart Cities. It is undoubtedly the area of protection of the health and life of residents, which has – so far – been treated as an undisputed and permanent component of urban existence, that does not require additional attention and improvement. Meanwhile, the unpredictability and uncertainty of the modern world in the last dozen or so months have completely negated this approach, which has become a direct premise for undertaking the considerations presented in this article.

Before identifying the directions of changes in the Smart City concept, an attempt was made to assess the interest in this concept in practice, using a survey conducted on a representative sample of Polish cities several months before the outbreak of the pandemic. The purpose of this analysis was to establish the legitimacy of dealing with the SC problem and to establish the role that health care has played in Polish cities so far.

The results of these studies, together with the conclusions resulting from the literature studies and the authors' observations, became the basis for indicating the directions of modification and improvement of the SC concept.
The research algorithm used in the article includes three stages:

1. literature studies in the field of research on the "smart-ness" of urbanised space, conducted in chapter 2,
2. conducting research on a group of Polish cities in terms of experiences related to the implementation of "smart" solutions and an analysis of the results of these studies focused on areas important in light of the experience of the pandemic,
3. indicating the necessary additions to the concept of creating and developing smart cities.

As part of the above-mentioned stages of research, answers were sought to the following questions:

1. What areas of a smart city have been considered the most important in the literature so far? Was research on smart cities sufficiently multifaceted (actually sustainable)? Did they refer to issues related to threats to human health and life – and to what extent?
2. Was the current concept of a smart city recognisable in practice in Polish cities and were the surveyed entities interested in its implementation? How did they assess the role of health protection in shaping the quality of life of city residents?
3. Which areas of the smart city concept can and should be strengthened and supplemented? How to improve the operation of smart cities in practice in the context of identified imperfections and conceptual deficiencies?

The research methodology used by the authors was adapted to the above-mentioned stages and research problems. In the first stage, literature studies covering the entire period of "constituting" the Smart City paradigm, that is the years 1996-2020, were used. The results of this stage are presented in chapter 2 of this study.

The second stage was carried out on the basis of a survey conducted in October 2019 on a representative group of 280 (out of 930) Polish cities, assuming a 95% confidence level and a maximum error of 5%. The selection of the sample was random. Such selected research parameters allowed for the formulation of conclusions in relation to the entire population of cities in Poland. The main objective of the research was to assess the level of development of smart cities in Poland, taking into account the interdisciplinary nature of smart city solutions. A side topic, covering several out of eighty-five survey questions, concerned the interest in the concept of SC in practice and was used in this article to emphasise the legitimacy of research and considerations regarding SC. In addition, the study uses a question about the state of health care in Polish cities, diagnosing the need and scope for introducing modifications and improvements in this area of functioning of Polish cities.

The survey questions were directed to people responsible for the creation and implementation of the city's development strategy, and the answers provided were validated in the form of conclusive answers ("yes", "no" or "I do not know") or on a five-point Likert scale.

The third stage of the research was conceptual and was based on the results of the two previous stages. The formulated observations related to the scope of additions and modifications to the current concept of a smart city, and related to practical solutions allowing them to be applied in the realities of an average city in Poland.

Research Results

Does anybody care about a Smart City? Assessment of interest in the SC concept in Polish cities

In accordance with the methodological algorithm presented above, the next research stage, after the literature studies, included surveying 280 Polish cities in October 2019. The main and primary goal of these studies was to identify the degree of implementation of smart solutions in classically defined development areas of a smart city, that is, taking into account the aspects of:

- technology and IT, including mobility and databases,
- economy and management,
- society,
- environment.

In the last part of the survey, the respondents were asked about their knowledge of the concept of a smart city defined in this way, evaluation of development in the context of area distinguishing features and smart city rankings, as well as the will to include the concept of a smart city in the development strategy of the area. In the current conditions, the questions asked allow to determine the degree of interest, knowledge and identification of Polish cities with the current vision of creating and developing smart cities.

The results obtained in this part of the survey were confronted with questions about the importance of the accessibility of health care in shaping the quality of life of the urban community and the difficulty of improving this accessibility. It made it possible to look at the health protection issues from the perspective of the current epidemic problems and to indicate the necessity and potential directions of redefining the smart city concept.

Figure 2 shows the distribution of answers to the survey question regarding the knowledge of the current concept of a smart city, which shows that over 65% of Polish cities surveyed know about the idea of a smart city, and only a few percent have never encountered it. Therefore, it is a recognizable concept, not only described in the literature on the subject, but also popularized in practice.

Fig. 2. Distribution of answers to the survey question regarding the knowledge of the current concept of a smart city.

Source: own study based on survey research.

Fig. 3: Distribution of answers to the survey question regarding the interest in obtaining the status of a smart city in the currently emerging and disseminated international rankings
Source: own study based on survey research.

Despite the declared knowledge of the concept of a smart city, only 1/3 of the surveyed entities are interested in obtaining the status of a smart city in the currently emerging and widely disseminated international rankings (Figure 3).

These are usually large cities that are striving to gain recognition, both domestically and abroad. A prominent place in the international ranking, the results of which are widely disseminated, would undoubtedly be a form of improving their image and attractiveness. However, ultimately only about 9% of the surveyed areas assess the degree of city development in the context of the current concept of a smart city, i.e. taking into account the following areas: technology and IT, including mobility and database, economy and management, society and environment (Figure 4). Cities are, therefore, aware of the existence of the smart city concept, to a large extent they are interested in obtaining the status of a smart city on an international scale, but they do not conduct or are unable to conduct a comprehensive assessment of the level of advancement in the implementation of smart city solutions. Nevertheless, over 27% declare that the smart city concept has been included in their development strategy (Figure 5), which clearly underlines the awareness of its importance in practice and the real interest in its implementation.

The obtained results were confronted with the answers regarding the importance of health care in cities, the distribution of which is presented in Figure 6. Over 87% of respondents consider the issue of accessibility of health care as very important or important for the quality of life in urban communities. Cities are, therefore, fully aware of the impact of health safety on the satisfaction of residents.

Fig. 4: Distribution of answers to the survey question regarding the overall assessment of the degree of city development in the context of the smart city concept so far

Fig. 6: Distribution of answers to the survey question regarding the importance of accessibility to health care in cities.

Source: own study based on survey research.

Fig. 7: Distribution of answers to the survey question regarding difficulties in improving the accessibility of health care in cities.

Source: own study based on survey research.

Unfortunately, they consider the tasks related to the improvement of accessibility of health care in cities as very difficult and difficult (over 64%). Only less than 10% of the respondents believe that they can be easy or very easy. This perception of health care in cities is probably one of the key reasons for ignoring public health issues in the smart city concept. The effects of improving accessibility and the level of health protection are difficult to achieve, costly and often require a wait for several or more years. It is also difficult to use them in an image strategy, because they relate to non-representative issues, such as: diseases, disability, old age or death. In addition, their guarantee and systematic improvement should theoretically be the primary, and not extra, element of the city's development.

The conducted research shows that Polish cities know the concept of a smart city, and some of them are interested in its practical implementation. Therefore, the issue of responsible definition and formulation of management recommendations for its implementation should be approached with great care. The overlooking and denial of the health problems of urban communities in the smart city concept may have catastrophic consequences, as evidenced by the currently spreading Covid-19 epidemic. Representatives of city authorities are aware of the importance of health issues, but – in practice – they indicate significant difficulties related to improving the scope and level of health care in cities. Including and exposing these issues to the concept of a smart city would make people aware of the fundamental nature of health protection in the existence and development of smart cities. It would also allow to create and promote good practices in this field on an international scale.

Proposals of new solutions and an analysis of the possibility of their implementation in areas of "smart cities"

The considerations presented above, based on the analysis of available literature sources, as well as the results of the conducted research, clearly indicate that the idea of smart urban space is still far from perfect. In the opinion of the authors of this article, the above statement is an obvious premise for the search for new and the improvement or supplementation of technical, organisational and managerial solutions that bring us closer to the state, in which the "smart city" retains the value of intelligence after the emergence of sudden, unexpected situations, as well as those causing a real threat not only for the classically understood well-being of residents, but also for their lives.

The following is a collection of ideas from the authors of this work, drawn from the experiences of the Covid-19 pandemic in cities. These ideas were organised into three groups:

A. a group of information and technical solutions,
B. a group of organisational and management solutions,
C. a group of "mixed" solutions (combining solutions from groups A and B).

In particular, in the opinion of the authors of this paper, solutions that fall into these three groups are:

A.1. Equipping the Smart City space with remote (automatic?) medical diagnostics systems, the structure of such a system to consider is: e.g. simple connections in each flat, connections in commercial premises, for a specific area (groups of premises, a point equipped with more extensive equipment and technical capabilities (e.g. operated daily and at least by a trained medical technician). A system with features similar to alarm and fire access control systems, with records, in flats: points for automatic measurement of body temperature. For privacy reasons: "arming" of the system should be done with the consent of the tenant/owner of the premises.

A.2. Establishing a network of local "emergency" warehouses with appropriate infrastructure (e.g. a solution similar to flood prevention equipment warehouses): first aid equipment, gloves, masks, water, food rations etc. in the event of quarantine.

A.3. Adaptation of IT infrastructure to increased (and changed) needs in emergency situations (Home Office, Home School).

B.1. Conducting an inventory of adapted facilities/rooms isolated from the rest of the SC space and development of plans for making rooms available in the event of a situation requiring access to the rooms.

B.2. Development of a map of roads (streets) and an initial record of transport systems to perform tasks resulting from the need to evacuate sick or quarantined people from the SC area.

B.3. Development of the existing infrastructure and management systems in the area of epidemiological and sanitary tasks.

B.4. Preparation of action plans aimed at maintaining the quality of life of SC residents in material, psychological and social terms during and after the end of threat.

B.5. Conducting epidemiological preventive and educational training that allows to reduce the scale of threats and strengthen social and professional responsibility during the emergence and escalation of threats.

C.1. Designing methods and preparing an appropriate technical infrastructure to enable universal and effective notification to residents about threats and the implemented mandatory emergency procedures.

C.2. Designing methods and preparing an appropriate technical and organisational infrastructure to support socially and economically excluded people (seniors, disabled, homeless, unemployed), especially in emergency situations.

C.3. Refining the existing procedures and preparing the appropriate technical and organisational infrastructure for the purposes of maintaining law and order, as well as preparing appropriate changes in such procedures for application (implementation) during natural or epidemic threats.

C.4. Development of the existing epidemiological and sanitary infrastructure and systems, including municipal infrastructure and systems, such as providing water to residents, sewage disposal and waste management, enabling the effective implementation of their tasks in emergency situations.

Summarising the above list, it is definitely not closed. Such a list must include all solutions ensuring that smart urban space not only retains its postulated value of providing residents with an appropriate level of quality of life, but guarantees maintaining (or perhaps improving?) this level. The more items this list contains, the greater the possibility of ensuring the implementation of the above-mentioned postulate.

It is worth noting that the problems indicated on the above list have already been taken up by researchers and described in publications (e.g. the "Smart Ambulance Service System" proposal, presented in (Sondur et al., 2015) or "Automatic Ambulance Rescue System" (Sangeetha, 2014)). However, the proposed solutions are "autonomously intelligent" in nature and were not considered to be a potentially integral part of the SC project.

In the opinion of the authors of this study, it is also impossible to ignore the real inclusion of the residents of smart urban space in both the process of shaping it and managing this space. The fact that this problem is important and has not been resolved so far (even without taking into account the effects of the pandemic) is evidenced by the extensive discussion of the scientific community, in which not only the issue of including, but even excluding citizens from the structure of a smart city (Engelbert, van Zoonen and Hirzalla, 2019) appears.

The design and implementation of the above proposed solutions also requires the development of efficient financing models at the level of operating (one-year) and strategic (multi-year) budgets. This task is very difficult, due to the following circumstances:

- the scope of necessary preventive actions covering many aspects of urban life,
- the scale of planned projects, which should cover the entire area of the city and all its residents,
- a drastic decrease in revenues in the city's budgets caused by a deep recession in the economy,
- limiting co-financing of municipal investments from private entrepreneurs, due to a sharp reduction in their income,
- no direct economic gains or image improvements resulting from the actions taken.

The development of a model for financing projects related to an epidemic threat – in accordance with the theory of public finance – should begin with clearly defining their nature and assigning them to one of the three categories of goods:

1. public goods that meet collective needs – by definition provided and financed under the public finance system (e.g. national defence, public safety, sanitary protection, road infrastructure, public administration),
2. social goods that partially satisfy collective needs and partially individual ones, the financing of which depends on the adopted political and social doctrine and the degree of economic development, and may be in the hands of the state or local government authorities, or be partially or completely in the hands of the citizens, in this case the residents of smart cities (e.g. education, health and culture),
3. private goods that only meet individual needs, the financing of which is provided by private households or enterprises.

Discussion

Most of the proposed projects are public goods and are directly related to the necessity to guarantee sanitary protection for residents, which guarantees that their physiological needs and the need for safety are met. Their financing should, therefore, take place in the sphere of public and local finances. However, the implementation of such an assumption in the current situation will certainly result in a long-term increase in public and local government debt, due to the mentioned reduction of budget revenues and the necessity to use debt instruments in the form of bank loans and treasury and/or municipal bonds.

Some of the above-mentioned activities can be treated in the category of social goods co-financed by city residents. This, in particular, applies to preventive education and individual pro-health activities. Some of them can also certainly be treated by residents as private goods, which, in order to increase their own safety, they will be willing to finance from their own resources, which will relieve the public and local government budgets.

It seems that, in this situation, the best models of financing will be hybrid models, in which funds from central and local budgets are combined with private funds from enterprises and residents. In this regard, you can use the already developed experience of sponsoring, public-private partnerships and the more and more popular idea of crowdfunding. At the same time, taking into account the nature of sanitary protection and public health, under which collective needs are financed, in the process of obtaining financing, the purpose of the actions taken and the individual benefits resulting from them should be highlighted. This is because the collective need for security is felt most strongly when the threat materializes and if the threat ends very quickly, it ceases to be important.

It should also be optimistically assumed, that taking far-reaching measures to strengthen sanitary safety and public health, generated as a result of the emergence of new individual and collective needs, will contribute to stimulating local entrepreneurship and economic life, which – in line with the Keynesian idea – will also enable the funding of local budgets and the gradual restoration of their financial potential.

In the existing concept of a smart city, the quality of life of its residents has been treated quite differently ((Macke et al., 2018), (Shapiro, 2006), (Vanolo, 2016)). Among other things, available works include a concept that identifies the quality of life in a smart urbanised area with satisfying higher "levels" in the hierarchy of needs (Tahir and Abdul Malek, 2016), (Goyal, Sahni and Garg, 2018), such as:

- the need to belong to an elite of the urban community,
- the need to be acknowledged as a citizen of the world, confirmed by the appropriate position of the place of residence in international rankings of smart cities,
- the need for self-realisation in any area of the functioning of a "smart" urban metropolis.

The Covid-19 pandemic has pushed the inhabitants of smart cities to the "lowest level" of the pyramid of needs (according to A. Maslov, these are physiological needs), focusing their attention on meeting their primary physiological needs (the need for health and the need to survive), at the same time depriving them of a sense of security. The state of epidemic threat triggered new needs (Lester et al., 1983), (Nicklowitz and Choi, 1994), the satisfaction of which would allow us to return to the current lifestyle in the future, provided a better health safety system was created.

The new needs, brought about by Covid-19, can be identified in the near future from the perspective of several key operational and preventive issues. Operational issues relate to all matters that need to be resolved during an epidemic threat and provide answers to the following ongoing questions:

- Are there any systems for monitoring epidemic threats and warning residents before their occurrence in a smart city?
- Do the smart city management principles allow for an effective policy of researching residents and equipping them with protection measures?
- Does a Smart City facilitate life in quarantine or facilitate the isolation of selected spaces?
- Do SC managers have developed procedures for systematic restoration of specific areas of socio-economic life?

Preventive issues relate to the principles of epidemic prevention and the functioning of the municipal health care system and answer the following strategic questions:

- Does the current Smart City provide better / more effective medical care?
- Does a Smart City ensure early detection of disease threats?
- Is the health care system in an SC effective and efficient in terms of medicine and finance?

The existing literature review shows that research on the above-mentioned issues has not yet been conducted in the context of SC considerations. Protecting the health and life of urban residents did not attract the attention of researchers, nor was it a priority in the hierarchy of needs. The leading places were occupied by technological and IT issues, which, on the one hand, were to improve the quality of life of the residents, and on the other to improve the financial performance of enterprises offering new infrastructure solutions. The needs of local communities, which were able to formulate, negotiate and implement them, also turned out to be important, although not the most important. The environmental needs turned out to be the least important, due to the weak and non-commercial voice of the communities representing them. However, in the present conditions, it would be advisable to build a pyramid of needs from scratch, i.e. starting from ecology, health and life protection, which can be subordinated to the functioning of urban communities, and the use of smart technological solutions.

Undoubtedly, it is a difficult task, if not impossible, because there are already attempts to return to the "old" habits and customs, as well as urban prosperity. Hence, according to the authors, there are strong reasons to redefine the SC paradigm and change the hierarchy of urban needs. Scientists and researchers can play the role of conscious informers and creators of the new reality in this process.

Conclusions

The current smart city concept has been systematically developed and improved in way of its sustainability and taking into account not only infrastructural, but also social and environmental aspects. In spite of that, very little attention and research was devoted to issues related to threats to human health and life, including epidemic threats.
The above observations are also confirmed by the results of surveys conducted in a group of 280 Polish cities, which prove the high recognition of the smart city concept, its importance in local development and the will to systematically implement technological, social and ecological activities displayed in it. These results also justify the conclusion that the issue of effective health protection is a priority in shaping the quality of life of the residents of smart cities. Nevertheless, improving the level of health protection in cities is a difficult and complex challenge, which is most likely one of the reasons for disregarding the inclusion of health issues in the conceptual area of improvement and development in smart cities.

Limited definition and implementation of smart city solutions has become the cause of activating the currently observed weaknesses of smart cities in the sphere of their real functioning and in the conceptual area, which – in turn – resulted in the need to redefine the idea of a smart city and supplement it with issues related to public health, including the assurance of effective sanitary and epidemic protection. Therefore, the authors of this study postulate that the role of public health in the concept of a smart city should be included and emphasised, as well as a number of practical solutions regarding epidemic threats, enabling the implementation of such a postulate divided into three groups: A. A group of information and technical solutions, B. A group of organisational and management solutions and a group of "mixed" solutions (combining solutions from groups A and B). The financing of these and other solutions could be most efficiently carried out using hybrid sources of capital, allowing to combine budgetary resources, investors' funds and the private involvement of smart city residents.

A Bibliometric Study of Renewable Energy and Circular Economy: Revealing Links and Dynamics

Nicolae PINTILIE

The Bucharest University of Economic Studies, Bucharest, Romania
pintilienicolae15@stud.ase.ro

Abstract

This paper aims to create an image of the relationship between circular economy and renewable energy through specialized papers published between 2000 and 2019. In this way, this paper is based on the study and analysis of the literature published on this topic in the last 2 decades. The paper also discusses how policies and measures towards circular economy can be integrated into the European body, with a positive effect on the society and environment. After the presentation of the methodology, the paper develops an analysis in time and space of the selected scientific papers, then an analysis of the keywords with their grouping on clusters, creating a map of them and highlighting the existing relationships. Moreover, the paper also presents a density map regarding the most important keywords used in the literature to develop the link between ”renewable energy” and ”circular economy”. Among the most interesting results are: (1) a massive concentration of works in the last three years of the period considered in the analysis; (2) Europe is one of the regions with the largest contribution in terms of authors; (3) The keyword map is particularly useful in revealing the link between keywords in the analysed context: the relationship between circular economy and renewable energy. Finally, the paper presents possible limits of the research, but also future directions of its development.

Keywords: renewable energy, circular economy, sustainability, waste management

Introduction

The circular economy is a concept that took off a few decades ago and is evolving day by day with articles and books published worldwide. Environmental factors that have put pressure on the environment are the main determinants that have contributed to the growing concerns for the circular economy as humanity manifests a growing demand for products, a demand that can be supported by a high consumption of resources.

Global warming and the rapid consumption of natural resources, respectively the desire to generate sustainable and competitive benefits determine us to oppose linear thinking (produce, consume, throw), moving towards a circular approach in which most of the materials used have another purpose at the end of the life cycle. In other words, making various investments in renewable energy involves a long process to analyze the most appropriate investment option, respectively to choose the best technologies, a process that involves re-engineering industrial entities and moreover, increasing environmental competitiveness for global and regional industry.

Climate developments in recent years have led people to adopt measures characterized by concepts such as sustainability or environmental protection. The traditional way of life has started to be “affected” by various factors, both climatic and social or economic, so that new ways of carrying out activities appear from one period to another.

Since ancient times, people have adapted to the conditions offered by the environment, using existing resources depending on where they were. It was later discovered that resources can be combined, the effect being much greater than their individual use. In this way, people began to form specialized communities depending on the resources in the area where they were located, having as object of activity resource processing. With the passage of

Cite this Article as: Nicolae PINTILIE “A Bibliometric Study of Renewable Energy and Circular Economy: Revealing Links and Dynamics” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

time and the diversification of activities, resources have started to begun increasingly scarce, so that in everyday activities began to feel the "limited nature of resources". At the same time, the processing methods have led to the appearance of effects that are felt over time, with an impact on the entire planet, effects that have begun to be felt by various phenomena, considered abnormal. Warming of the Earth's atmosphere, the occurrence of strong storms and landslides, illness for unjustified reasons, all these are effects that sum up the way resources in various territories have been exploited and processed through organized activities, without taking into account (consciously or unconsciously) the impact on the whole world.

The current economic activity is based on the linear model of production and consumption: in this sense, the main industrial and commercial activities are characterized by the phrases “to extract / produce”, respectively “to consume / throw away”. Moreover, with the passing of each year, natural resources are increasingly depleted and the amounts of garbage generated are more and more consistent, so that in the traditional economic model is truncated reference to optimizing materials through recycling, reuse or recovery. If, in addition to all these elements, we also discuss the fact that energy is needed to carry out the activities of companies (industry, trade, etc.), which is usually based on fossil fuels, then we can consider that the transition from the traditional economy to the circular economy can also be based on the transition from conventional to renewable energy, produced by environmentally friendly means. Renewable energy is an energy of the future due to the very limited nature of traditional resources, but there can be no conversion of energy production globally without highlighting the need to fundamentally change the entire flow of production and handling of products and services transmitted to the market.

Literature Review

Several literature review have been carried out in the field of circular economy. Most research have focused on the desire to define the concept of circular economy and also outline how to implement it in business models and new technologies (Geisdoerfer, et al., 2017; Kirchherr et al., 2017; Pan, et al., 2015; Tukker, 2015). However, given the novelty of the concept, the socio-economic potential and the impact on the environment following the conversion of the traditional economy to the circular economy is not yet understood at the macro level (on national, multinational and global scale) (Wiebe et al., 2019; McDowall, et al., 2017).

Nowadays, more and more resources are considered critical, and their depletion is becoming more and more rapid over the years. Global economic activities are represented by the linear model of production and consumption (produce - consume - throw), and these concepts in combination with the production factors mentioned in the literature (labor, nature, capital) lead to the generation of goods and services within a single life cycle. (Rodriguez et al., 2020). In the linear consumption model presented above, the end user has the responsibility to take care of the disposal of the product, which leads to products accessible to all consumers, but at the same time to waste resources and significant amounts of garbage (Ellen MacArthur Foundation, 2015).

Given the implications and effects of the circular economy, decision-makers or other stakeholders in all countries have been attracted to this concept, which is increasingly being transposed into true national policies. The circular economy is an innovative concept that has the power to develop new business opportunities and economic growth while respecting the environment, being an alternative to the current model of production and consumption. In this way, through the transition to the circular economy, waste could be seen as the new resource of the economy, which can lead to the reduction of pressure on critical resources and also the reduction of garbage quantities. (Rodriguez et al., 2020).

The premise that the use of fossil fuels (coal, natural gas, oil) leads to economic growth has been widely debated in various papers. However, a significant amount of carbon dioxide is released into the atmosphere due to the high use of non-renewable resources, with severe implications for the greenhouse effect. The economic development that mankind has known in recent years has been based on the use of polluting energy sources, this statement being supported by data from the World Resource Institute, which shows that more than a third of greenhouse gas emissions are generated by traditional energy sources (Shahbaz et al., 2020). This has led to negative effects on society as a whole and on the environment, air pollution being an important cause for various health problems. Nowadays, any country must rely on renewable energy sources (hydropower, geothermal energy, solar energy, wind energy, biomass, etc.), and it is necessary to develop these alternatives in a sustainable way, which will ultimately lead to pollution reduction.

In 2013, renewable energy accounted for 19.1% of global final energy consumption. According to the data, the electricity sector is fueled by both increases in renewable energy production (solar panels, hydropower, and wind energy) and increases in energy production resulting from the use of oil, coal and natural gas. At this point, specialists around the world need to lay the groundwork for a system that increases the share of renewable energy

use to replace traditional energy consumption, with notable effects for sustainable economic growth (Shahbaz et al., 2020).

If we are to discuss the concept of circular economy, the first appearances were at the end of the last century, in the ’80s works were written about this notion (Bassi & Dias, 2019). In fact, according to Bassi & Dias (2019) the key of the circular economy concept is the harmonization between economic growth and environmental protection, although many definitions have been noted in the literature. In this way, we can highlight the work of Kirchherr et. al (2017) who conceptualized the notion of circular economy, analyzing 114 definitions. According to Ellen MacArthur Foundation (2015), the circular economy is an industrial economy that is established or regenerated by intention and design. Taking this affirmation into account, we can say that the transition to a circular economy for the world industry does not mean reducing the means of production or limiting production, but rather the reconfiguration of production processes taking into account aspects related to environmental protection.

Homrich et al. (2018), and Reike et al. (2018) define the circular economy as an economic system that develops to oppose the traditional system (produce, consume, throw), in order to achieve sustainable development, with significant effects on environmental quality, economic prosperity, social equity. In this context, the concept of the circular economy is of great importance given that the European Commission itself is making significant efforts to support the transition to a more sustainable, low-carbon, resource-efficient and competitive economy. In this spirit, at European level we can remark Scottish Institute for Remanufacture (Great Britain) and also Institut de l’Economie Circulaire (France) whose purpose is to provide assistance to industrial actors wishing to adopt this concept in their production and supply chains (Suzanne et al., 2020).

According to Forbes Romania, there is great potential for Central and Eastern European countries in terms of renewable energy. In fact, it is stated that "renewable energy is the cheapest source of mass electricity production for Poland, the Czech Republic, Romania and Bulgaria" (Forbes Romania, 2020). Under these conditions, the study of existing investment opportunities for Europe and the world on renewable energy and the circular economy, respectively highlighting the number of jobs that could be created, are factors of major importance that deserve to be studied, given the effects such as economic recovery, lower carbon emissions, increasing the competitiveness of industrial activities.

Circular economy in Europe: how to increase developing through environment care

The circular economy is a growing concept worldwide, specialists currently analyzing the implications that this type of economy can have on human activities. The main advantage of the circular economy is the attention to the energy system, energy sources being an important component in the process of the circular economy.

At European level, the most comprehensive document attesting to the European Union's orientation towards the requirements of the circular economy is the EU Circular Economy Action Plan, launched in 2015. Moreover, at EU level there is a tendency to accelerate the conversion to a sustainable development model, in which resource consumption is closely monitored, reducing anthropogenic footprints on the environment. In addition to environmental issues, the EU is also set to create a framework for the business environment, designed to bring sustainable products to market, and also to assure new oportunities. According to the European Commission (2015) the potential for GDP growth for the EU economy is 0.5% by 2030, with the possibility of creating over 700,000 new jobs.

The circular economy is a concept that includes several areas, of similar importance, which can be seen in Figure 1.

Fig. 1: A simplified model of the circular economy for materials and energy

One of the main aspects highlighted by Figure 1 is the reduction of waste quantities, but also of raw materials through activities such as eco-design, recycling, reusing.

All this can contribute to increasing economic and environmental benefits, provided that the dependence on imports and resource extraction is reduced in close connection with the reduction of emissions from resource extraction, resource processing, waste incineration.

No activity can be performed without access to an energy source. For this reason, all the activities in Figure 1 are included in a sphere called „Energy". In other words, the conversion of the traditional economy to the circular economy cannot be achieved without increasing the efficiency of the energy system and increasing the share of renewable energy (European Environment Agency, 2016).

In fact, at the level of the European Union there is a similar evolution of the share of energy from renewable sources and private investment, jobs and gross value added related to circular economy sectors, the trend being highlighted in Figure 2.

Fig. 2: Evolution of share of energy from renewable sources and activities related to circular economy sectors

At the European Union level (28 states) from one period to another the share of energy used from renewable sources increased from 13.41% in 2011 to 17.47% in 2017, which indicates the concern of decision makers and the socio-economic environment to replace traditional energy means by using alternative, more environmentally friendly sources. At the same time, value added from activities related to the sectors of the circular economy at EU level increased by over 17% from 2011 to 2017, from EUR 131.905 million to EUR 154.790 million, this fact being explained by the change of the paradigm at European level regarding the assimilation of the concept of circular economy, with advantages on various levels: economic, social, environmental.

Although the trend of the two indicators exemplified by figure 2 is similar, in their analysis we went through the stage of determining the correlation coefficient using the Microsoft Excel computer system, Correl function.

Period	Private investments, jobs and gross value added related to circular economy sectors (million Euro)	Share of energy from renewable sources (%)
2011	131.905	13,411
2012	132.707	14,69
2013	132.669	15,378
2014	140.429	16,219
2015	145.797	16,732
2016	146.743	16,995
2017	154.790	17,474
Correlation coefficient		**0,904**

Fig. 3: Correlation coefficient

The correlation coefficient determined based on data from 2011 to 2017 between Private investments, jobs and gross value added related to circular economy sectors and Share of energy from renewable sources is positive and very close to 1, which expresses a direct correlation, so we can affirm that the two indicators values evolve in the same direction. Thus, based on the data we can emphasize that an increase in the use of energy from renewable

sources will increase the value added in activities related to the circular economy, in other words at EU level renewable energy can be seen as a pillar of support in view of the transition of economic activities to the circular economy.

In other words, the circular economy brings into question at least 4 benefits, shown graphically in Figure 4, benefits that can be achieved according to availability to pay some costs:

Fig. 4: The circular economy benefits

a) Resource benefits – resource efficiency is a key step in adopting the circular economy. An eloquent example of this is the improvement of waste management, which can be secondary raw materials for economic activities, thus reducing the pressure on global resources characterized by the limited nature. At EU level, improving waste management can have an immediate effect on reducing import dependence, which can help increase the protection of the European business environment from price volatility in international goods markets or reduce uncertainty about the possibility of delivering a certain resource, located at a considerable geographical distance (European Environment Agency, 2016). According to Meyer (2011), streamlining the use of resources through innovations could reduce material consumption at EU level by around 24% by 2030, given that it is currently estimated that between 6 and 12% from the consumption of materials is avoided after recycling, waste management;

b) Economic benefits – The circular economy is largely based on innovation, both in the field of technology and in the field of business models, generating competitiveness and added value superior to the traditional economy in which various opportunities are not considered for economic reasons. Investments in elements that shape the circular economy involve a consumption of monetary resources, but ensure an increase in competitiveness by reducing the consumption of resources, with long-term sustainable effects. According to Amec Environment & Infrastructure and Bio Intelligence Service (2014) at the level of EU member states, net benefits are estimated between EUR 245 billion to EUR 604 billion, representing an average of 3 - 8% of annual turnover following the adoption of measures such as waste prevention, material recovery, modification of procurement activities, modification of products;

c) Social benefits – circular economy involves changing traditional thinking, in order to increase the sustainability of consumer behavior by improving health and safety. In other words, the adoption of the circular economy is estimated to create more than 178,000 new direct jobs by 2030, with a significant impact on the welfare of the population (European Environment Agency, 2016). Depending on the field of activity, the circular economy implies the emergence of new trades, both for white-collar and blue-collar, given that the circular economy is based on innovation through the development of technology and research, but also through the redesign of daily activities related to construction, manufacturing, waste management, etc.;

d) Environmental benefits – reconfiguring traditional energy production systems and rethinking waste management can make a significant contribution to reducing greenhouse gas emissions, with a direct effect on the environment and the population. Moreover, according to Amec Environment & Infrastructure and Bio Intelligence Service (2014), increasing the efficiency of resource use through appropriate measures in areas such as food and drink, fabricated metals, hospitality and food services sectors can avoid about 100-200 million tons of emissions CO2 equivalents, which means about 5% of EU emissions in 2018 (Eurostat, Greenhouse gas emission statistics - emission inventories, 2020).

Materials and Methodology

In order to ensure the methodological transparency of this bibliometric analysis focused on the relationship between circular economy and renewable energy, the authors applied a systematic review process in close accordance with other publications of this type (Popa & Gora, 2020; Cicea et al., 2019; Gora, 2019; Marinescu & Cicea, 2018).

The first step of this article was to define the problem that would be studied, that is „What are the links between circular economy and renewable energy taking into account the worldwide literature in the field"? After establishing the purpose of the study, the next step was to select the database with publications based on which we can develop a data set suitable for bibliometric analysis. For this purpose, the WoS (Web of Science) database was chosen and used, to select the scientific papers that contain the two terms to be analysed, our arguments being the compatibility with the analysis software, but also the exhaustiveness of the data set.

After choosing the database, the third step involved the documents selection taking into account the English language. In this way, 286 documents were identified in the mentioned database, which simultaneously deal with the phrases "circular economy" and "renewable energy". The year 2020 was removed from the analysis because it is not a full year, and the analysis interval was 2000-2019; subsequently, only "article", "conference paper", "book chapter" and "review" documents were considered. As a result, 282 documents remained to be analysed in order to perform the bibliometric analysis.

Finally, the analysis that are to be performed following the stated methodology:

- STAGE 1 – Analysis of the geographical and temporal distribution of scientific production in the field - on the one hand, through this analysis we want to observe how the publications in the field have evolved taking into account the regional measures adopted by the authorities, and on the other hand we wanted to see which are the geographical areas of interest in order to implement the circular economy.;

- STAGE 2 - Semantic analysis of keywords - this stage aims to identify the correlations between circular economy and renewable energy in terms of words derived from the two concepts, respectively which are those subdomains that are influenced by publications and how close this influence is;

- STAGE 3 – Identifying significant clusters based on keywords - through this stage we are trying to see the areas of interest for research aimed at achieving circular economy in correlation with renewable energy. Moreover, this analyse is very important to understand what implications there are regarding transition to circular economy through renewable energy taking into account that these two concepts include a lot of other subdomaines.

To carry out the research, documents were downloaded from the WoS database containing the following characteristics: title, year of publication, authors, abstract, keywords; all this information was used in the VOSviewer program.

In order to be able to visualize the bibliometric analysis, the VOS Viewer software was chosen and used, in which the distance between two nodes indicates their correlation and moreover taking into account the number of citations the words have, the bigger the nodes are (Waltman & van Eck, 2014).

Results and Discussion

In accordance with the phases above outlined, we will first analyse the temporal and the geographical spread of the scientific production. Thus, using the WoS database, we obtained the following annual distribution of documents, graphically represented in Figure 5. Despite the fact the we selected the documents between 2000 and 2019, we found out that database containing the mentioned key words have publications starting with 2009. This first analyse shows us that the relation between circular economy and renewable energy is just at the beginning. The 2009-2014 period of time reflects a relatively hesitating and long beginning of the research regarding circular economy and renewable energy. However, since 2015 till 2019, the number of papers included in the main flow of publications grew semnificatively, showing the growing interest for the concerned theme. What is more, the last two years of the analysed period account for almost 64% of the total number of the articles considered in this study.

Fig. 5: Timeline of the scientific production

Looking closer at the graphical representation within Figure 5, we can observe one turning point in the literature specific to circular economy and renewable enegy. This milestone is at the level of 2015, the point reflecting an increase in the scientific production, which is directly connected to the researchers interest for this theme and indirectly related to national, regional and global policies that promote environmental protection.

Going further, the geographical distribution of the scientific production will be analysed, by studying the affiliation of the first author or, by the case, of the corresponding author. Figure 6 is designed as a tree-map. Each branch contains the number of authors affiliated to an institution or organization from a specific country, so the size of a "leaf node" (the rectangle) is proportional to this number.

As the tree-map confirms, the main source of the scientific production is Italy, accounting for more than 19% of the analysed documents with 56 authors. It is followed by The People's Republic of China with 32 and Germany 44 authors. What is more, this first four countries are home for around 41% of the total number of authors (343).

In terms of keywords analysis, this was undertaken with help of VOSViewer software. In order to obtain valid results, the authors removed from the analysis the two collocations after which the Web of Science database was queried: "circular economy" and "renewable energy". The keywords occurrences for the 282 articles subject to this analysis are presented in the table 1.

Fig 6. First author or corresponding author's affiliation by country

Table 1: Top 20 keywords ranked after occurrences

Nr. crt.	*Keyword*	*Occurrences*	*Total link strength*
1	Sustainability	46	156
2	Life-cycle assessment	41	155
3	Energy	38	125
4	Biogas	23	102
5	Anaerobic-digestion	26	101
6	Bioenergy	22	96
7	Biomass	26	92
8	Anaerobic digestion	20	80
9	Management	22	71
10	Systems	18	70
11	System	17	67
12	Municipal solid-waste	14	64
13	Waste management	17	64
14	Biogas production	11	59
15	Co-digestion	10	53
16	Performance	19	53
17	Recycling	15	68
18	Food waste	11	65
19	Water	13	65
20	Bioeconomy	12	64

Table 1 also reveals the total link strength for each keyword, showing in this way the keywords power to connect to other identified keyword. For instance, "Sustainability" appears 46 times within the articles and creates 156 links with other keywords, while "Life-cycle assessment" appears 41 times and manages to connect as it reports 155 links. The least connected keywords are "Co-digestion" and "performance".

An even more suggestive situation was generated in VOSViewer based on the grouping of keywords in clusters (from the total number of keywords, only those that have a frequency of occurrence of at least 5 times, were

considered). This grouping is visually designed as a map which includes each cluster, the nodes and the branches linking the nodes.

The largest cluster is the red one, composed out of 17 keywords, followed by the green one with 9 nodes and by the blue one with 7 nodes. The size of each node is given by the number of occurrences of that keyword, so larger a bubble, greater the number of keyword's occurrences. The position of each keyword within the network represented in Figure 7, shows how likely it is to find two keywords in the same context. For instance, "bioeconomy" is positioned as a keyword in the upper half of the network, while „recycling" appears in the lower half of the map, so their connection within articles is very low or perhaps never found together in the discussed context.

Fig. 7: Grouping keywords in clusters

Looking once again at the network shown in Figure 7, we can observe the most used words in three areas of focus; "Sustainability", "Energy" and "Life-cycle assessment" are bigger nodes than other ones, meaning that the importance of these three keywords within the research field of circular economy and renewable energy, is high. "China" is the single keyword from the map (at the left part of the red cluster) referring to a country, while "biomass" and "biogas" are bringing into attention well-knows ways in order to produce green energy.

If we examine the keywords assigned to each cluster, we can observe that they tend to highlight specific features or related meaningful concepts related to the relationship between circular economy and renewable energy. The blue cluster refers mainly to environmental issues and ways to reduce the negative impact on environment, while the green cluster focuses on processes through waste can be converted into energy. The red cluster is more complex as it seems to include methods to act in a sustainable manner, taking into account management implications and also existing policies regarding environmental protection.

Another important VOSViewer analysis regards density visualization (see Figure 8). Each node in the density visualization map has a color that relies on the density of items at the node. In other word, if the number of items in the neighborhood of the node is big, than the colour of a node is more bright. For our situation, the keywords in yellow colour area appear more frequently in the research area; on the other hand, the keywords in green colour area appear less frequently. Figure 8 is very important for our bibliometric analysis because we understand the overall structure of Figure 7; the reseach realized in the field of "circular economy" and "renewable energy"

focuses on “Sustainability”, “Energy”, “Life-cycle assessment”, these keywords being core keywords in most of the 282 papers selected.

Fig. 8: Keywords density visualization map

Conclusions

The current study has a contribution in understanding the role of renewable energy in the circular economy practices as it was seen through the publications between 2000 and 2019. Within this paper, the construction of the graphs has revealed salient features of renewable energy – circular economy research in time. By grouping keywords in clusters we were able to see the links between different terms existing in the same context, revealing that it is a big possibility to have a lower correlation between a modern concept such as „bioeconomy” and a way to deal with waste management such as “recycling” word. Taking this situation into account, a further paper can take into consideration the role of recycling in the transition to bioeconomy. Moreover, based on the Figure 7, there are three types of concepts that can have an influence on the relationship between renewable energy and circular economy: the methods used by the society to produce green energy, the framework in which the society acts in order to assure the conversion to circular economy and the environmental problems which can be solved only by giving up the traditional way of doing things (produce – consume – throw).

Taking into account Figure 5, we can say that the topic of the paper is at the beginning stage, so there is enough room to bring about tremendous improvements of the research in the field, between 2018 and 2019 being published almost 64% of the total number of the articles considered in the present paper. It is also important to mention that from one period to another this topic is brought to people's attention through a scientific form, in last years the activity being intense. Moving at the Figure 6, there is clear for us that the topic of our paper is a central one in Europe, but also in China, this regions representing the main source of the scientific production. On the other hand, we can highlight that there are also countries from all around the world which are interested in studying this topic, mentioning here USA (18), Brazil (9), or India (6), etc.

Even though the authors explained in detail the methodology used within this paper, the study has some limitations. First of all, only WoS database was used in order to obtain articles. A similar analysis could be conducted using other databases, such as Scopus, which may influence the number of selected articles and provide other query options. Second, each tool used to arrange results in a specific way (see keywords map or tree-map) has its own configuration. It depends only on the ability of authors to learn how to use other software tool too. Third, the relationship between renewable energy and circular economy is just at the beginning, specific issues about these concepts will be in the light of researchers attention, so this may constitute a future research direction revealing ways of transition through circular economy.

Acknowledgment

This paper is a result of the research conducted through the 2020 – 2023 Doctoral advanced research program at The Bucharest University of Economic Studies.

Abstract

The paper includes a description, formulation, and method of the solution to a certain problem related to the optimization of the structure of parcel distribution system in a chosen logistics company. It was assumed that the parcels should be generated in the zip code areas (more precisely - we know the shipment volume between each pair of zip codes in a time profile (day/week/month/year)). The issue of the system structure optimization is decomposed into two sub-issues: (1) location and dimensioning of the company's branches by optimizing the number, location, capacity of the branches and allocating zip code points to be serviced by the branches. The optimization criterion is the total cost of establishment and maintenance of the branches as well as the cost of transporting of the parcels from zip code points to the branch and vice versa; (2) location and dimensioning of the sorting plant and determination of the transport plan. The issue number (1) was solved using a modified randomized method for k-means clustering on the current data on the structure and volume of shipments from a certain courier company. The results of the research based on the real data have been described.

Keywords: optimization of the distribution system structure, k-means clustering, regionalization, hub location problem.

Introduction

The issues related to the so-called regionalization and optimization of the parcel distribution system are typical for, among other things, courier companies and require cyclical problem-solving (Barreto et al (2007)). To formulate and solve such issues, advanced methods of operational and artificial intelligence research are used. The scale of the problem and many limitations that need to be considered make researchers apply methods of data mining and IT technologies for the processing of Big Data (Chowdhury et al (2017).

The issue tackled in the article may be classified as the *Hub Location Problem* (HLP) (Farahani et al (2013)). The hubs are devices operating as points of consolidation, connection and switching of transfers between specific transfer sources and final destinations. The aforesaid transfers may refer to travelers, objects, or information (in case of ICT networks). The hubs are used to reduce the number of direct connections between the sources and final destinations. The reduction process leads to a decrease of the resource consumption and hence reduction of the transfer system costs. The HLP already has a long history. It seems that the ICT industry was the first one to implement the concept of hubs (Farahani et al (2013)). Currently, it is widely used in the logistics systems, passenger air travel, postal and courier companies. The HLP is reflected in many ways due to different conditions. In addition, many scientific papers devoted to the optimization of hub location were written. Therefore, many overview studies have been carried out to give a clearer and more logical order to the achievements in this area. Papers by Alumur & Kara (2008), Farahani et al (2013), O'Kelly & Miller (2004) are some of the most insightful studies in the field. The HLPs may be classified according to a number of different aspects:

- space where the hubs are allocated. Three possible cases are taken into consideration: discrete - network nodes (the only locations are nodes of the known network for the transfer of goods); limited discrete - a set of predefined transfer network nodes; continuous - the hubs may be allocated to any place on the surface or in space;
- method of taking account of costs: minimization of costs related to the transportation of goods from their sources to final destinations; minimization of the total system costs, including transportation expenses and the cost of establishment and maintenance of hubs;

Cite this Article as: Zbigniew TARAPATA and Ryszard ANTKIEWICZ "Model and Algorithm for Hub Location Problem in Selected Courier Company" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- number of hubs: the systems with one hub; the locations of the predefined number of hubs are analyzed; the number of hubs is a decision variable, whose value is determined in such a manner so that the system costs are reduced;
- hub capacity limitation: in case of theoretical issues, hubs with unlimited capacity are analyzed, whereas all application studies assume that all hubs have limited capacity. The hub capacity may be determined as the decision variable as part of the optimization problem;
- allocation of nodes other than hubs to hubs. Two cases are considered: each node allocated to one hub; each node may be allocated (processed) by more than one hub.

  An important element of the HLPs are methods for solving the analyzed optimization problems. Due to a multitude of formulations of the HLPs, there is a wide diversity of algorithms for their solution. A list of problems and an overview of the applied algorithms may be found in the overview studies: (Alumur & Kara (2008), Farahani et al (2013)). The information on the selected methods of clusterization and optimization of transport is also included in Tarapata (2011). Generally, the methods may be divided into the following categories:
- precise – producing optimum solutions, including linear and non-linear programming methods, integer linear programming methods, Benders' decomposition methods, stochastic programming methods;
- approximate/heuristic – simulated annealing (Yu et al (2010)), Tabu search, ant colony optimization algorithm, genetic algorithms, Monte Carlo simulation, others (Yu & Maghfiroh (2014)).

The problem discussed in the article is a part of larger solution (Tarapata et al (2020)) and may be classified as a hierarchic HLP, with continuous space of hub location and minimization of the total cost of the system implementation, including the transportation expenses and the cost of establishment and maintenance of hubs, where the number of hubs is determined during the optimization process, while allocating each node not being a hub to one hub, with the consideration of the limited hub throughput. While talking about the hierarchic problem, it is assumed that there are two levels of hub hierarchy: sorting plants – connect hub-branches and hub-branches that process direct nodes not being hubs. An example of the model and optimization process of the hierarchic system is in (Gendron & Semet (2009)). It seems that the problem formulated in such a broad manner has not been analyzed in the literature known by the authors. What is more, the applied method of solution consisting in the decomposition of the problem and use of the modified clustering algorithm for allocating the nodes – zip codes to the hubs-branches constitutes a new element in the field of HLP.

The article is organized in the following manner. In next chapter, the authors described the decision problem and formulated the optimization problem related thereto. Further chapter contains a description of the method of problem solution and some results of the analysis, using the implemented method. Finally, the authors presented their conclusions and a summary.

Description and Formulation of the Problem

The problem defined in the article occurs while designing the hierarchic structure of the parcel distribution system composed of: sorting plant, branches and customers (pick-up/delivery point). The system allows to pick up parcels from customers-senders, deliver it to regional branches, where it is grouped and sent directly to the branch-recipient or sorting plant, where it is sorted and then sent to the recipient's branch, where the parcels are eventually dispatched to the customer-recipient. It was assumed that the shipment should be generated in the zip code areas (more precisely - we know the shipment volume between each pair of zip codes within the time frame (day/week/month/year)). The issue of optimization of the hierarchic system structure is decomposed into two sub-issues: (I) location and dimensioning of the company's branches by optimizing of the number, location, capacity of the branches and allocating code points to be serviced by the branches. The optimization criterion is the total cost of establishment and maintenance of the branches as well as the cost of transporting shipments from code points to the branch and vice versa; (II) location and dimensioning of the sorting plant and determination of the transport plan including: generation of potential location of sorting plants for the set structure of the branches (e.g. set in sub-issue (I)), optimization of the location and dimensioning of the capacity of the sorting plant for the volume set between the branches and sorting plant as well as the choice of an optimum location of the sorting plant and transportation plan. In the subsequent part of the article, the authors discussed in detail sub-issue (I).

The following notations shall be used:
M – the number of zip code points;
$wspX_i$, $wspY_i$ – the location (coordinates) of the center of the i-th zip code point, i=1,…,M;

a_{ij} – the volume sent from the *i*-th to the *j*-th code point; on the basis of such data, it is possible to calculate the volume "entering" ($b_j^{in} = \sum_{i=1}^{M} a_{ij},\ j = 1,...,M$) the *j*-th zip code point, "leaving" it ($b_j^{out} = \sum_{i=1}^{M} a_{ji},\ j = 1,...,M$) and total volume "passing through" the *j*-th zip code point ($b_j = \max\left\{b_j^{in}, b_j^{out}\right\},\ \ j = 1,...,M$);

w^{in}, w^{out} - coefficients of proportionality related to the cost of delivery (*in*) to and from the branch (*out*) (delivery to customers);

c_k – the unit cost (per work time unit) of operation of the *k*-th type of vehicle, k=1,…K, where K designates the number of types of vehicles;

cu_n – the unit cost (per capacity unit) related to the construction/maintenance of the *n*-th branch, n=1,…,N, where N designates the number of branches; the cost may be also presented in the form of a function.

The decision variables in the formulated optimization problem are the following:

N – the number of branches;

x_{nj} – the binary variable meaning allocation of the *j*-th zip code point to the *n*-th branch, n=1,…,N, j=1,…,M;

y_{nj} – the binary variable meaning location of the *n*-th branch in the *j*-th zip code point, n=1,…,N, j=1,…,M;

The cost of construction and maintenance of the *n*-th branch (warehouse and sorting plant) may be set in the following manner:

$$g(n,x,y) = cu_n z_n = cu_n \sum_{j=1}^{M} y_{nj} \sum_{k=1}^{M} b_k \cdot x_{nk}, \quad n = 1,...,N \tag{1}$$

where: $x = \left[x_{nj}\right]_{NxM}$; $y = \left[y_{nj}\right]_{NxM}$

and z_n designates the capacity of the *n*-th branch:

$$z_n = \sum_{j=1}^{M} y_{nj} \sum_{k=1}^{M} b_k \cdot x_{nk}, \quad n = 1,...,N \tag{2}$$

In case of all branches, the total cost of their construction and maintenance equals:

$$\sum_{n=1}^{N} g(n,x,y) = \sum_{n=1}^{N} cu_n z_n = \sum_{n=1}^{N} cu_n \sum_{j=1}^{M} y_{nj} \sum_{k=1}^{M} b_k \cdot x_{nk} \tag{3}$$

The cost of transport from all code points allocated to the *n*-th branch if the *n*-th branch located in the *i*-th zip code point is:

$$f^{in}(n,i,x,y) = y_{ni} \cdot \sum_{j=1}^{M} c_1 w^{in} d_{ji} \cdot \frac{b_j^{out}}{q_1} \cdot x_{nj} \tag{4}$$

where d_{ij} designates the distance between zip code points *i* and *j*, i=1,…,M, j=1,…,M,

$d_{ij} = \sqrt{(wspX_i - wspX_j)^2 + (wspY_i - wspY_j)^2}$. On the basis of formulation (4), it is evident that in case of a single branch, it is the total cost, based on all zip code points, related to the selected vehicle (the smallest, index 1, hence c_1 or other selected) that covered the distance between the zip code point and the branch and the number of vehicles (b_j/q_1) of such capacity intended for the transport (q_1 designates the capacity measured by the amount of the transported volume in case of the selected vehicle with index 1).

The cost of transport to the *n*-th branch is equal to:

$$f^{in}(n,x,y) = \sum_{i=1}^{M} f^{in}(n,i,x,y) = \sum_{i=1}^{M} y_{ni} \cdot \sum_{j=1}^{M} c_1 w^{in} d_{ji} \cdot \frac{b_j^{out}}{q_1} \cdot x_{nj} \tag{5}$$

The cost of transport from the *n*-th branch to all allocated zip code points if the *n*-th branch in the *i*-th zip code point (6) and the cost of transport from the *n*-th branch (7):

$$f^{out}(n,i,x,y) = y_{ni} \cdot \sum_{j=1}^{M} c_1 w^{out} d_{ij} \cdot \frac{b_j^{in}}{q_1} \cdot x_{nj} \tag{6}$$

$$f^{out}(n,x,y)=\sum_{i=1}^{M} f^{out}(n,i,x,y)=\sum_{i=1}^{M} y_{ni}\cdot\sum_{j=1}^{M} c_1 w^{out} d_{ij}\cdot\frac{b_j^{in}}{q_1}\cdot x_{nj} \tag{7}$$

The cost of service in the n-th branch is calculated in the following manner:

$$f^{serv}(n,x,y)=w^{serv}\cdot\left(f^{in}(n,x,y)+f^{out}(n,x,y)\right) \tag{8}$$

where w^{serv} is a coefficient of the service cost in the branch.

The total cost of transport to all branches shall be as follows:

$$\begin{aligned}
&\sum_{n=1}^{N}\left(f^{in}(n,x,y)+f^{out}(n,x,y)+f^{serv}(n,x,y)\right)=\\
&=\sum_{n=1}^{N}\left(f^{in}(n,x,y)+f^{out}(n,x,y)+w^{serv}\cdot\left(f^{in}(n,x,y)+f^{out}(n,x,y)\right)\right)=\\
&=\left(1+w^{serv}\right)\sum_{n=1}^{N}\left(f^{in}(n,x,y)+f^{out}(n,x,y)\right)=\\
&=\left(1+w^{serv}\right)\sum_{n=1}^{N}\left(\sum_{i=1}^{M} y_{ni}\frac{c_1}{q_1}\sum_{j=1}^{M} d_{ij}\cdot x_{nj}\left(w^{in}\cdot b_j^{out}+w^{out}\cdot b_j^{in}\right)\right)
\end{aligned} \tag{9}$$

The optimization problem related to the choice of the number of branches, their location and allocation of zip code points to be serviced by the branches for the purpose of reduction of the total costs of transport from zip code points to the branches as well as the costs of construction and maintenance of the branches shall be as follows (sum of (3) and (9)):

$$\begin{aligned}
&FK(x,y,N)=\left(1+w^{serv}\right)\sum_{n=1}^{N}\left(\sum_{i=1}^{M} y_{ni}\frac{c_1}{q_1}\sum_{j=1}^{M} d_{ij}\cdot x_{nj}\left(w^{in}\cdot b_j^{out}+w^{out}\cdot b_j^{in}\right)\right)+\\
&+\sum_{n=1}^{N} cu_n\sum_{j=1}^{M} y_{nj}\sum_{k=1}^{M} b_k\cdot x_{nk}\rightarrow\min
\end{aligned} \tag{10}$$

with the following limitations:

- each zip code point must be allocated to exactly one branch:

$$\sum_{n=1}^{N} x_{nj}=1,\quad j=1,\dots,M \tag{11}$$

- each zip code point allocated to the branch may not be located at a distance (within a radius) greater than the set boundary value R:

$$\sum_{n=1}^{N} dd_{nj}x_{nj}\le R,\quad j=1,\dots,M \tag{12}$$

where $dd_{nj}=\sum_{i=1}^{M} d_{ij}y_{ni},\quad n=1,\dots,N,\ j=1,\dots,M$.

- the location of every potential branch must be determined in exactly one zip code point:

$$\sum_{j=1}^{M} y_{nj}=1,\quad n=1,\dots,N \tag{13}$$

- maximum one branch must be allocated to each zip code point:

$$\sum_{n=1}^{N} y_{nj}\le 1,\quad j=1,\dots,M \tag{14}$$

$$y_{nj}, x_{nj} \in \{0,1\}, \quad n = 1,...,N, j = 1,...,M \tag{15}$$

It should be noted that the so formulated optimization problem is a non-linear problem (due to the form of a goal function), with binary variables. The number of decision variables is $2MN$, the number of constraints is equals $3M+N$. The method for solving the formulated problem is presented in the next chapter.

Description of the Method of Problem Solution

The proposed algorithm for setting the location of the branches and allocation of zip code points to the branches for the pre-set number of N branches is a modified, randomized algorithm of k-means, where the distance used for clustering is defined in different ways. The optimum number of branches is chosen by initiating the algorithm for various N values and the target function (9) assumes the lowest value for such a solution.

The algorithm has been described below.

0. Determination of the number of N branches.

In case of the predefined number of repetitions (i.e. epochs), the following activities should be undertaken:

1. determination of initial centers of clusters (branches).

The centers of clusters (i.e. centroids) are selected in several ways. The cluster center referred to the center of the geographic zip code region (after zip code twos or threes, see Fig. 1). The manner of setting this region (whose center was the cluster center) depended on the epoch.

- 1.1. In case of the first epoch:
  - 1.1.1. generation using distribution of the probable proportionate volume:
    - 1.1.1.1. according to code twos
    - 1.1.1.2. according to code threes
  - 1.1.2. Generation with equal probability distribution (independent of the volume)
    - 1.1.2.1. according to code twos
    - 1.1.2.2. according to code threes
- 1.2. For the next epoch:
  - 1.2.1. generation using distribution of the probable proportionate volume:
    - 1.2.1.1. according to code twos
    - 1.2.1.2. according to code threes
  - 1.2.2. Generation with equal probability distribution (independent of the volume)
    - 1.2.2.1. according to code twos
    - 1.2.2.2. according to code threes
  - 1.2.3. Random modification of the region locations (coordinates) used in the first epoch (*delta_x, delta_y*)

2. Calculation of the distances of code points from the cluster centers.

The choice of metrics is a very important element of the algorithm. Two metrics (distances) between code point i and cluster center j were used:

- 2.1. the Euclidean distance d_{ij}
- 2.2. the volume-weighted d_{ij}^{weight} distance: $d_{ij}^{weight} = d_{ij} \cdot \frac{c_1}{q_1} \cdot \left(w^{in} \cdot b_j^{out} + w^{out} \cdot b_j^{in} \right)$, see (4) and (6)

3. allocation of zip code points to clusters.

In case of each zip code point, the distances from all clusters (calculated in point 2) are compared and allocated to zip code points, i.e. to the closest center.

4. Determination of new cluster centers.

The new cluster centers are calculated in two ways:

- 4.1. Arithmetical mean of coordinates of the points allocated to the cluster
- 4.2. Volume-weighted mean of coordinates of the points allocated to the cluster

5. Performances of steps 2, 3, 4 until the stop condition for the epoch is fulfilled.

The stop condition for the epoch requires to meet one of the following requirements: achievement of the predefined number of iterations (usually N), i.e. repetitions of steps 2, 3, 4, or no movement of zip code points between the clusters and subsequent iterations.

The best allocation of zip code points to the clusters after all iterations should be saved.

6. If the last epoch is reached, that means the end – the best saved allocation to the clusters constitutes the solution to the problem; otherwise, the user should go to point 1.

Analysis of Results

The studies were conducted using the data from one of the courier companies. Because the authors of the article did not obtain the consent to make available the actual data and obtained results, the presented results were derived from the modified data.

Fig. 2 shows a map of code threes, including the input and output data volumes (parcels) aggregated therefor (based on the provided values: a_{ij}). The total data volume (input and output) used for the purpose of analysis was approx. 800 000. The number of all zip codes, between which the paired volume was used, (a_{ij}) equaled to M=20153 in a given period. Such number of zip codes were then allocated to the branches. The analyses were conducted for number N of the branches presented in the left column of Table 1. Therefore, the optimization problem had from 2·20153·30 to 2·20153·80 binary decision variables and from 3·20153·30 to 3·20153·80 limitations. On the basis of historic data analysis, it was calculated that the correlation between the coefficients w^{in} and w^{out} in formulas (4)-(7) was: w^{in}/w^{out} = 1/3, and w^{serv}=0,47 (formula (8)). It was assumed that the capacity q_1 of the vehicle equaled to 600, and the cost coefficient was c_1=1,13. The parameter R, present in formula (12), was calculated in the following manner: $R=(v_{sr}\cdot T_{max})/2$, where v_{sr}=50 km/h (average speed of delivery vehicles), T_{max}=8h (maximum working time of a vehicle driver). While calculating R, the product $v_{sr}\cdot T_{max}$ was divided by 2, since when the driver leaves the branch for servicing code points, the driver must also come back to such branch during their working hours.

Table 1 contains the results of the algorithm for setting locations of the branches and allocation of zip code points to the branches in the form of the total cost of transport from/to the zip code points from/to the branches for the representative day in the month. The number of epochs was equal to 50, whereas the number of iterations in every epoch – 20. While generating the first epoch in accordance with the probability distribution depending on the volume (point 1.1.1. of the algorithm), point 1.2.3 of the algorithm was implemented, i.e. random change of coordinates of the cluster generated in the first epoch - *delta_x*=100km and *delta_y*=100km. The calculation time on a standard PC took from a few seconds to several tens of minutes.

(a) (b)

Fig. 2: Map of regions for the zip code threes in Poland, including analyzed *in* b_j^{in} (a) and *out* b_j^{out} (b) volumes to/from each of the *j*-th region. The darker the color, the greater the volume. The total *in* and *out* volumes were approx. 800 000.

Source: own elaboration

As shown in Table 1, the determination of locations of the branches based on the volume-weighted distance function allowed for better allocation than in case of the simple Euclidean distance (total cost of delivery lower several times). On the other hand, the generation of cluster coordinates in all epochs according to the distribution depending on the volume improved the cost function by around 10% in comparison with the generation of only the first epoch with the distribution depending on the volume.

Fig. 3 illustrates locations of the branches, their capacity and allocation to the zip code points to be serviced by 65 branches from Table 1, set based on all epochs generated in accordance with the probability distribution depending on the volume.

Fig. 4 shows functions of the monthly costs of transport to/from the branches and maintenance costs of the branches estimated based on data and results obtained from the algorithm. The values in the last column of Table 1 were multiplied by 25 (number of working days in a month, from Monday to Saturday) to obtain the estimation of function (9) in the form of $4 \cdot 10^7 \cdot N^{-0,559}$. The function related to the costs of construction and monthly maintenance of the branches (3) was proposed by cost experts specializing in maintenance of logistics infrastructure and has the following form: $758\,777 \cdot N^{0,4697}$. Both functions are shown in Fig. 4a. Fig. 4b shows the total costs from Fig. 4a. The function assumes the minimum value for the number of branches, which is equal to 55, hence, based on the presented analyses - the optimum number of branches is 55.

Table 1: The results of the algorithm for setting locations of the branches and allocation of zip code points to the branches – the total cost of transport from/to the zip code points from/to the branches for the representative day in the month.

Summary

While formulating and solving the problem described in the article and after discussions with the experts specializing in the logistics organization, certain conclusions and observations were made. First, to make informed decisions about the future of the system structure, it is essential - in our opinion - to have data allowing to forecast changes in the distribution of volumes between particular zip code points (code areas, voivodeships).

In case of optimization of the number of branches, it is also important to include the transportation costs for the locations of the branches: without considering courier routing, the numbers are merely estimating. It is crucial to have a matrix of road distances between the zip code points and average speed of movement (the authors used the following estimation: road distance = geographic distance *1.3 and average speed from the parameter vśr=50 km/h) or a matrix of average duration of the transit between the zip code points. Therefore, the approach considering both issues is often found in the literature (Barreto et al (2007)). The cost of the branch construction and maintenance (as the capacity function or, potentially, the location function) is also an important factor, which the companies may estimate based on historical data. Minimum and maximum throughput limits in the branch, e.g. due to limited space available in the locations, should be also considered. Similar remarks refer to the sorting plant (the issue of location and dimensioning of the sorting plant may be solved in a similar manner to the issue of location and dimensioning of the branches).

Abstract

In the paper we look at the issue of tax aggressiveness from the perspective of enterprises that, in accordance with the provisions of Polish tax law, may establish a tax capital group (TCG). Focusing on companies from banking sector we study, to what extent such an entity can reduce its tax liability and how profitable a creation of TCG vehicle can be. In order to answer the question we use individual tax data provided by companies with annual turnover above EUR 50 million and all Polish tax capital groups. For years 2012–2019, we calculate the annual effective tax rates achieved by the largest taxpayers from the banking sector. In the next step, we compare the tax rates achieved by single entities with those reported within banking tax capital groups. In order to deepen the research, we additionally calculate the average annual effective tax rates of both groups: single companies and banking TCGs. The results of the study show that the vehicle of tax capital group is rarely used by Polish companies operating in the banking sector, nor leads to the reduction of their tax liabilities.

Keywords: Tax Aggressiveness, Tax Group, Group Taxation, Tax Risk, Tax Avoidance.

Introduction

The sources of instruments that enable the reduction of tax burden can be divided into two categories. The first category groups the decisions of taxpayers aimed at reducing or shifting the tax burdens. Such optimization activities take place within the solutions permitted by law. The second category groups the actions of the legislator who, by appropriate drafting of legal regulations, makes the use of specific tax preferences possible. As a consequence, the legislator shapes the economic reality: through the proper implementation of tax policy, it leads to the achievement of previously set goals.

One of the tools implemented by Polish legislator is the possibility of joint taxation of companies, organized into the tax group. Legal tools enabling the consolidation of several separate enterprises' tax results are allowed in many jurisdictions. In such construction the economic benefits are typically ensured by the application of domestic group taxation regimes (also referred to as fiscal unity, tax grouping, group tax relief or joint taxation) through which losses/costs of one company can be offset against the taxable profit of other company belonging to the group. As a rule, the joint taxation is a critical factor for the tax benefit of the structure (European Commission, 2015).

So far, the studies on the use of Polish tax groups in the tax optimization process were undertaken to a very limited extent. The launch of official publication of data on income and tax paid by the largest domestic taxpayers (including tax capital groups), made it possible to investigate, to what extent the Polish group taxation regime can lead to the reduction in tax liabilities. For the purposes of our study, we have chosen the banking sector, as it is characterized by the largest representation of taxpayers whose individual tax data has been made public.

Tax groups in Polish Tax Regime

In Poland, the group taxation regime is regulated by art. 1a of the Corporate Income Tax Act (CIT Act). It introduces the construction of tax capital group (TCG), where a group of companies, after meeting certain conditions, can be treated as a single taxpayer for the purposes of corporate income tax. Tax capital groups may only be established by

companies with the registered office in Poland and with an average share capital of at least PLN 500,000. The parent company must hold 75% of the shares in the subsidiaries, and subsidiaries may not hold shares in other members of the group. None of the companies may be exempt from corporate income tax. The tax capital group must be established for at least three tax years and it is not possible to extend the TCG's agreement to include other companies in the group. Additionally, group members must not have any tax arrears. During the entire period of existence of the tax capital group, the minimum share of income in the revenues of the tax group should be 2%. What is worth mentioning, in case of breach of certain conditions, the tax capital group loses the status of taxpayer retroactively (from the date of registration as a tax group) and companies forming the tax group are obligated to reconcile for CIT purposes as independent taxpayers retroactively for prior years (*Corporate - Group Taxatio*n, 2020).

As mentioned above, Polish TCG offers companies a possibility of consolidating financial results for income tax purposes within a group. However, due to the stringent requirements of the applicable laws, tax capital groups are not a very popular means of consolidation for tax purposes in Poland. Consequently, studies on tax capital groups, concluded in Poland, are rather of a general nature.

Furman (2015) in his work presents legal requirements to be fulfilled in order to exclude individual companies from the tax subjectivity. He also studies the historical changes in the number of registered TCGs and in income tax amounts, paid in 1996–2013. In the same time Wierzejska (2015) investigates the motives for creating tax capital groups. She shows that non-tax benefits (in the area of cash flows, movement of assets or acquisition costs between companies) may support the decision to form a group. In the research Wierzejska confirms a relatively poor use of TCG structures in Poland. She points out that this may result from both a number of shortcomings in Polish regulations and significant consequences in the event of failure to meet the conditions during the existence of the TCG.

The tax effectiveness of Polish TCGs has not yet been the subject of in-depth research. Kondrakiewicz (2010), focusing on the municipal sector, investigates one case of Tax Capital Group of the Kraków Municipal Enterprises. She finds out that the joint settlement of corporate income tax can actually bring significant benefits, as in twelve years of operation the analysed Group have recorded over PLN 92.5 million of tax savings.

Małecka-Ziembińska (2014) in her research presents the evolution of Polish TCG regulations and next examines the fiscal impact of the introduced modifications. She proves that changes in the conditions for the establishment and operation of tax capital groups affect the number of active TCGs, and thus the amounts of income tax that they pay. Małecka-Ziembińska concludes that despite the severe TCG's requirements, the possibility of offsetting individual profits and losses and the neutrality of transactions concluded between companies may constitute the basis for tax optimization.

The use of tax capital groups for the purposes of aggressive tax planning did not go unnoticed also at the political level. On June 26, 2017, the Ministry of Finance issued a warning about corporate income tax optimization practices, done within Polish tax capital groups. According to the ministry, transactions carried out with the use of such regimes included assets worth many billions of zlotys (Polish Ministry of Finance, 2017).

The growing role of tax optimization practices result in anti-tax avoidance measures, implemented by (mostly) developed countries to their national legal systems. Poland has also adopted some solutions, aimed at increasing tax transparency. One of them is the obligation to publish individual data of largest taxpayers (with revenues exceeding EUR 50 million) and all tax capital groups. The Amendment to the Polish CIT Act introduced a new art. 27b providing the publication of individual tax data of 4,500 CIT taxpayers with the highest revenues and all TCG (regardless of the amount of revenues), which are formally recognized groups of wholly or majority-owned companies consolidating their taxes under a single Polish entity. The individual tax data to be published by the Ministry of Finance includes information on: taxpayer's name, tax identification number (NIP), revenues, tax deductible costs, income or incurred loss, tax base and tax due. In addition, the published information may be extended with data on the effective tax rate. The provisions apply to taxpayers' data from January 1, 2012. Publication of these data to the public first took place on September 30, 2018.

Better access to information of large taxpayers draw out attention to Polish tax capital groups. We have decided to use methods applied in previous research on tax aggressiveness of Polish companies as a basis for further analyses (Brodzka, Biernacki, Chodorek, 2017; Brodzka, Biernacki, 2018). In the present study we define the tax aggressiveness of enterprises that, in accordance with the provisions of Polish tax law, may establish a tax capital group, and next we examine the impact of introducing the vehicle on overall income tax burdens.

The individual data of largest taxpayers available on the website of the Ministry of Finance allows for comparing a homogeneous group of taxpayers. Consequently, for further analyses we select companies from banking sector, which play significant role in the whole group of those entities, whose fiscal dates are being published. Our purpose was to answer a research question: to what extent such an entity can reduce its tax liability by establishing a tax capital group? In order to answer the question we calculate the effective tax rates achieved by banks that report within single taxpayers group and next, we compare these results with effective tax rates reported by tax capital groups operating in banking sector.

Methodology and Data

Polish CIT Act provides for an annual publication by the Ministry of Finance of individual tax data of both CIT taxpayers with the revenues exceeding EUR 50 million and all tax capital groups. Data from individual taxpayers' returns refer to 2,801 entities, whereas the TCG' ones deal with 65 tax groups.

As a measure of tax efficiency we choose the effective tax rate, developed previously by Guenther, Matsunaga and Williams (2013). Researchers, in order to study a relation between the tax policy of the enterprise, affecting the amount of regulated fiscal burdens and the tax risks taken, use the concepts of tax avoidance and aggressive tax practices, which afterward are compared to the accompanying risk of dispute with tax authorities. Guenther, Matsunaga and Williams adopt a cash effective tax rate (Cash ETR) received by comparing the amount of the tax paid in a given period with the income before taxes and special items as a measure of tax avoidance. They point out that low effective tax rates mean the ability of the company, in the long term, to reduce the amount of the tax due from each cash-generating unit, before taxation. As such the results show the level of tax avoidance, succinctly defined as taking solutions within the applicable law, intended to lead to a reduction of the income tax paid by the company. Cash ETR may be estimated on an annual basis, but earlier studies of Dyreng, Hanlon and Maydew (2008) recommend the use of five-year-period data for the comparison in order to obtain a better picture of tax policies applied by the business entities. Also in our study the methodology is based, in the wake of the work of Guenther, Matsunaga and Williams, on a comparison of the current amount of tax paid in a given fiscal year with the annual income reported for tax purposes.

For the purposes of our research the tax amount is recognized as the total tax liability paid in a given year, regardless if its source. The choice of annual income and not the tax base allows for avoiding possible discrepancies related to reliefs or exemptions, as the amounts and principles of deductions may differ from one taxpayer to another. This solution also minimizes the impact on the current result, resulting from offsetting tax losses from previous years.

We take into account a relatively long, eight-year research period of reporting the individual tax results (2012–2019). From the group of the largest single taxpayers, we select entities from the banking sector and – for each consecutive year – we compute their ratios of tax paid to the value of the income showed in annual tax declarations. Next we do similar calculations for banking groups reporting within TCG regime. Such a long period adopted for the purposes of our analyses allows for excluding both fluctuations related to business cycles and minimizing the effects of deferred taxation and tax loss settlements.

The choice of the banking sector for research purposes is justified by a large number of banks that report individual tax data in both groups: single taxpayers and tax capital groups. Among 2,801 single entities, the banking sector is represented by as many as 72 taxpayers. In case of TCGs, there are seven banking groups out of 65 taxpayers.

In case of the first group, of single taxpayers, we excluded those enterprises that did not provide tax data for at least two tax years. We also did not take into account companies in the liquidation and bankruptcy process. Additionally, we excluded Bank Gospodarstwa Krajowego from the further analyses. The bank carries out tasks commissioned by public authorities, hence its tax data does not come only from economic activity. As a result, in the first group we conducted analyses on 54 entities.

While studying the second group, TCGs, we excluded two banking groups that reported losses throughout the entire research period. Thus, we analysed the results of five tax capital groups.

Results

As mentioned above, for the analyses in the group of single companies reporting the individual tax data we chose 54 entities operating in the banking sector. The effective income tax rates achieved by largest banks are presented in the Table 1. In the table, the years of reported losses are marked with the value '0'; no data provided in the given period has been marked with (–). The list of entities presented in this table is arranged by their tax identification numbers (NIP), however, for the clarity of the data, the NIP numbers are not shown in its content. The exception is Deutsche Bank Polska, which operates in Poland both as a bank and as a branch of the parent company (thus, we have left NIP numbers with each of Deutsche Banks).

Source: Authors' own research based on the data published by Polish Ministry of Finance

The data presented in the table above show that the effective tax rates in the group of single taxpayers stay close to the nominal tax rate of 19%. Even if in the initial years of the study a specific company reports s a significantly lower effective tax rates, in subsequent years its effective rates practically coincide with the nominal one. Apart from the years when some taxpayers report a loss, the lowest effective tax rates achieved by some banks are close to zero (e.g. Raiffeisen Bank Polska S.A. in 2013). Moreover, in the entire research group there are no entities whose effective tax rate would exceed the nominal rate. It can bring us to a preliminary conclusion that the national legislation allows banks for reducing the tax burdens without the need to establish a TCG.

While examining the single taxpayers' group we noticed that some banks (IDEA BANK S.A. and Powszechna Kasa Oszczędności Bank Polski S.A.), first reported the tax information as single taxpayers, and next, after some years, decided to establish a tax capital group. In the further part of our study, we examine whether a decision of using the TCG vehicle for tax settlements brings some tax benefits. The effective tax rates, reported by tax capital groups operating in banking sector in years 2012–2019, are presented in the Table 2.

Table 2: The effective income tax rates of tax capital groups from banking sector in years 2012–2019

	Tax Group	2012	2013	2014	2015	2016	2017	2018	2019

Source: Authors' own research based on the data published by Polish Ministry of Finance

The analysis of the aforementioned data shows that the group taxation is not a very popular solution among banking enterprises. In the analysed period, only three banks decided to establish the TCG. As indicated earlier, in the initial period, two entities first reportedtax information as single taxpayers and next decided to establish the TCG (IDEA

BANK S.A. and Powszechna Kasa Oszczędności Bank Polski S.A.). One enterprise operated as a tax capital group during the whole research period (Bank Millennium S.A).

Due to the national regulations, which allow the establishment of TCG only for a maximum period of three years, we present each banking group in the table as a separate TCG. Such step is justified by the fact that individual groups are identified by separate tax identification numbers and – more importantly – the next TCG of the same bank may consist of different entities. Thus, for the sake of the study, we cannot present groups established by the same bank, but in different periods, as one tax capital group.

After analysing the results of groups one and two we cannot confirm that introducing the tax capital group has a positive impact on overall income tax burdens. Among TCGs, most entities achieve the effective tax rates below, but very close to the nominal rate of 19%. However, one TCG pays tax according to effective tax rate higher than the nominal one. In this case, it is questionable to what extent establishing such a vehicle is economically justified, if it ultimately leads to an increase in the effective tax rate.

The small number of entities that decided to establish the TCG encourages for an in-depth analysis of their results. The only bank consistently operating in the form of a tax capital group is the Bank Millennium S.A. Its TCG achieves annual effective tax rates at a very similar (although lower) level than the nominal tax rate. The only exceptions are years 2015 and 2016, when the group ended up with tax rates of 19.13% and 19.00%, respectively. The lack of visible tax benefits did not prevent Bank Millennium from the decision to create another tax group and next, from achieving the effective tax rates slightly below the level of 19%.

The analyses of next two cases question even more the possibility of optimizing the tax burden with the use of tax capital groups. In years 2012 and 2013, IDEA BANK S.A. provided for tax information as an individual taxpayer and achieved relatively low effective income tax rates (14.17% and 17.47%, respectively). Since the establishment of TCG in 2014, the effective tax rates for the entire IDEA BANK group started to increase significantly, reaching values higher than the nominal tax rate. The next tax capital group established by IDEA BANK S.A. in 2017, achieved an effective tax rate of 22.1% and was dissolved in the following year.

The bank Powszechna Kasa Oszczędności Bank Polski S.A., in the years of reporting the tax data as a single taxpayer (2012–2018), achieved effective tax rates at the level between 16.93% and 18.90%. In its first year of operating as the tax capital group (2019), the average tax rate increased to 18.94%. We assume that to the newly formed TCG a profitable individual enterprises was included, in order to offset its tax revenues in the account of the entire group.

The in-depth investigation of all TCG cases leads to the conclusion that for entities operating in banking sector the establishment of a tax capital group does not bring significant tax benefits. In order to confirm this assumption we additionally study the overall ability of banks to reduce the amount of the tax due by using the TCG mechanism. For each consecutive year we determine the average effective tax rates for all entities in the group one (single taxpayers) and in the group two (tax capital groups). The results of the analyses are presented in the Table 3.

Table 3: The effective income tax rates in banking sector–values for single taxpayers and tax capital groups

Year	Single taxpayers	Tax capital groups
2019	18.77%	18.93%
2018	18.87%	18.92%
2017	18.66%	19.16%
2016	18.36%	19.14%
2015	18.10%	19.14%
2014	18.58%	19.00%
2013	17.68%	18.99%
2012	17.55%	18.99%
AVERAGE	**18.39%**	**18.99%**

Source: Authors' own research based on the data published by Polish Ministry of Finance

The analyses show that during the whole research period the average effective tax rates achieved in the group of single taxpayers were lower than in the case of tax groups. What is worth mentioning, the effective tax rates in the group of single taxpayers were gradually increasing, while in the case of TCG a reverse tendency is visible.

It should be emphasized that the data in Table 3 does not include loss settlements, previously presented in Table 1 with the value of '0'. This is a deliberate action, resulting from efforts to maintain the comparability of the calculations presented in Tables 1 and 3.

The results presented in Table 3 provide additional confirmation of our initial conclusions resulting from the analyses presented in Tables 1 and 2. Despite the fact that the differences in the average effective tax rates between single taxpayers and tax capital groups are very minor (they do not exceed 1,5 percentage point), the direction of these differences is surprising: the average effective TCG's tax rates are higher than the rates reported by single taxpayers operating in the banking sector.

Although the number of banking tax capital groups in the analysed period is very small compared to the group single taxpayers, the comparison presented in Table 3 shows a continuing tendency, that confirms the lack of economic rationale for the use of Polish tax capital groups.

Discussion and Conclusion

The results of the study show that the option of establishing a tax capital group in Poland does not lead to a reduction in the tax burden – at least not in the banking sector. The conducted analyses prove that the difference between the average effective taxation of single taxpayers and of entities forming TCG is negligible. Moreover, the average rates of effective taxation are higher in case of banks operating in the form of tax capital groups.

Such results pose an obvious question about the sense of creating TCG for enterprises from banking sector. Consolidation of results of various entities for the purpose of the joint taxation is reasonable only when some taxpayers forming the TCG bring a loss in financial terms. In such a case the income of other units allows for the current and effective use of losses. In case of banks, analysed in the group of single taxpayers, another trend is apparent: despite losses reported by individual entities, they is no interest in establishing tax capital groups. Moreover, the TCGs already operating on the Polish market, do not report any reductions in total corporate income tax burdens, in comparison to the single taxpayers.

The lack of the effect of reducing the tax burden by establishing the TCG results in a little use of this form of tax optimization. It can be illustrated by a comparison of the number of taxpayers from the banking sector who settle their accounts independently, with the number of tax capital groups. Consequently, we can assume that Polish regulations enabling for group taxation, do not result in increased interest in the consolidation of several separate enterprises' tax results.

From the perspective of the state budget, the existence of TCGs does not reduce the flows of tax revenues. Thus, a conclusion can be drawn that Polish provisions on group taxation are fictitious: this instrument, used in many jurisdictions, is admittedly legally allowed in Poland, but the strict conditions of its use do not bring significant tax reductions for taxpayers.

In order to generalize the conclusion that tax capital groups do not have any influence on Polish strategies of minimizing tax burdens, it is necessary to analyse other areas of the economic activity. Nevertheless, in the banking sector, the legal possibility of establishing the tax capital group is not perceived as the effective solution, that can lead to a significant reduction of the income tax paid by the company.

[1] The Amendment to the Polish CIT Act introduced a new art. 27b providing the publication of individual tax data of 4,500 CIT taxpayers with the highest revenues and all TCG (regardless of the amount of revenues), which are formally recognized groups of wholly or majority-owned companies consolidating their taxes under a single Polish entity.

Abstract

Aadhaar Enabled Payment System (AePS) is a payment method that is widely used in India. This paper assesses and evaluates AePS payment system. It was introduced and established by National Payments Corporation of India(NPCI). This payment method helps in performing electronic transactions using Micro ATMs. It crosschecks the Aadhaar numbers and biometrics of the respective customer. The focal point of this paper is to acquaint public, the impact of AePS on digital payments in India. This is done by examining various literatures in Indian scenario. AePS has developed a powerful digital payment network. Real time verification of biometrics and Aadhaar number is done in this payment network. The main aim of this system is to promote financial inclusion. Now AePS is currently in a developmental stage. RBI and NPCI have made significant steps in discovering new areas to improve the payment system networks. AePS has helped in preventing illicit payments and also helped in blocking unauthorized direct benefit transfers.

Keywords: Digital payments, National Payments Corporation of India, Aadhaar Enabled Payment System, Biometric, Micro ATM

Introduction

According to International Monetary Fund's report on India, Indian Economy is the fastest growing economy in the world (International Monetary Fund Report, 2019). As per World Bank report on India, India's GDP stood at 2.5 trillion. In India, 66% of the people live in rural areas (World Bank U.N. Rural Population report, 2019). Here more transactions are done in cash. So India is cash driven economy. There is more dependency on cash. It leads to many problems like fake currency, tax evasion etc and management of cash is difficult.

Reserve Bank of India is the central bank. It has taken steps to avoid these sorts of problems. For cashless payments and digitalization of payments, National payments Corporation of India was formed in 2008. National Payments Corporation of India(NPCI) is an organization which operates digital payments and it provides infrastructure for overall banking systems in India. Aadhaar Enabled Payment System (AePS) was introduced by NPCI in November 2010. It is a payment System which uses Aadhaar authentication and biometrics for payments transactions at Micro-ATMs through the Business Correspondent (BC) of any bank. First step is to identify the beneficiary that is related to the respective account and biometric verification is done using the Aadhaar. We need to link our Aadhaar and bank account for doing transactions. AePS is made inorder to do ONUS based transactions and OFFUS based transactions.

According to reports of NPCI, AePS has crossed 220.18 million transactions in July 2019. RBI has taken many steps to promote digital payments. As per the Mary Meeker's report of Internet Trends 2019 India's share of internet users is 12 %.(Mary Meeker's report on Internet Trends,2019)

The purpose of this paper is to analyse the technological advancement of AePS. AePS has shown tremendous growth in recent years. The AePS provides services like withdrawing cash, balance enquiry, depositing cash, funds transfer, mini Statement etc.

Cite this Article as: Abhimanyu Sasi Pavoor and N. Ajithkumar "AePS – A step forward: Indian Perspective" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Background

The payment system in India has made significant changes due to advancement in technology. Indian economy is growing at a faster rate. Now we are living in a digital world. Everything is going online. India is basically cash driven economy. Several services are offered by many financial institutions to promote digital payments. The main services offered by NPCI are RuPay, IMPS(Immediate Payment Service), BHIM(Bharat Interface for Money), AePS(Aadhaar Enabled Payment System), UPI(Unified Payments Interface), NETC(National Electronic Toll Collection), NACH(National Automated Clearing House), CTS(Cheque Truncation System), Bharat QR, BHIM Aadhaar, NACH(National Automated Clearing House), * 99# etc. After demonetization many reforms came into existence in Indian economy. Now people are more concerned about speedy and secured settlement of transactions. Cashless mode of payment is now popular among common man. Due to introduction of smart phones and new technological innovations, people use such phones for faster payments. The apps in smart phones help in faster settlement of transactions. Aadhaar has proved to reduce corruption to a certain extent in India. The leakage in tax and other unparalled economy can be controlled by enrolling in Aadhaar. Schemes like NREGA and public distribution system became more effective. Recently Aadhaar bill was introduced. Reserve Bank of India established 2 working groups. One working group was made on Micro ATM standards and the other was on Central Infrastructure Connectivity. Reports were submitted to RBI by these working groups. AePS Steering committee includes 21 banks. The banks that are included in steering committee are Yes Bank, Union Bank of India, United Bank of India, State Bank Of India, Syndicate Bank, Saraswat Co-Operative Bank, Ratnakar Bank Limited, Punjab National Bank, Oriental Bank of Commerce, Indusind Bank, IDFC Bank, ICICI Bank, Fino Payments Bank, Central Bank Of India, Canara Bank, Bank Of Maharashtra, Bank Of India, Bank of Baroda, Axis Bank, Allahabad Bank, Andhra Bank etc. NPCI is giving instructions to participating banks for daily reconciliation of AePS transactions. NPCI audits the AePS of the related banks which are members of AePS and the related business correspondents.

Review of literature

Bhakti et al. (2017). This article discusses about Aadhaar pay. Initially people were more familiar with BHIM. Hence inorder to make Aadhaar Pay popular government named 'BHIM Aadhaar Pay' before its launch. Business people need a smartphone with Aadhaar pay app installed and a bank account. Sellers have to pay at merchant discount rate for these transactions. The aim of this app is to help people who are not comfortable with digital transactions and use Aadhaar to authenticate biometrics.

Bhatti, B. (2012). In the article Aadhaar enabled payments are portrayed with special concentration on NREGA labourers. Biometrics is used in AePS. It has helped to prevent corruption.

Ashwin Manikandan (2019). In this Article he opined that AePS transactions have increased. Micro ATM is the system which is more used in rural India. 100 million people are using their biometrics for doing transactions in local kirana stores. AePS Growth rate has increased to 150% annually. It has crossed UPI. NPCI report points out that almost Rs 9000 crore worth transactions are done using Micro ATMs. 800 Million customers are using AePS. This is just because the government linked Direct Benefit Transfer (DBT) through AePS. Private sector banks are more concentrating on AePS in different states namely West Bengal, Madhya Pradesh and Uttar Pradesh, Rajasthan, Bihar and Odisha.

Sharmin, K. I. (2020). In this research paper the author elaborated about AePS and its innovations. This paper also discusses about different mechanisms of AePS and its effects on digital payments.

Objectives of the Study

1. To assess the effectiveness of Aadhaar payment System.
2. To analyse the impact of AePS on Cashless payments.
3. To review the safety concerns of AePS.

Research Methodology

The study was according to the objectives stated above. Based on the objectives data was collected from secondary sources and analysis was done based on that. The data was collected from various journals and different websites of govt. and other organizations. Reports and Circulars of Reserve bank of India and circulars and orders of National Payments Corporation of India helped in scrutinizing and interpreting the data.

Types of Transactions in AePS

ON-US transactions

ONUS transaction is done at the ATM of the bank that issues the card. In these types of transactions, the transactions can be completely prepared within the bank which is an acquiring bank as well as an issuing bank. Banks may utilize their very own validation method if biometrics are accessible with the bank, or use Aadhaar confirmation as a fallback.

OFF-US Transactions

This transaction is done at the ATM of other banks not from the bank where the card is issued. In these types of transactions, the transaction is done by a client through the agent that is linked with the bank other than the clients own bank, to process the transaction the clients Aadhaar number will not be adequate. All clients are given a BIN number which is 6 digits long which prefixes the Aadhaar number in these types of transactions.

Objectives of AePS

1. **To promote financial inclusion**
   AePS helps in proper accounting of transactions. Every transaction done online leaves a documentary proof. So it can reduce black money. It is helpful for the customer as well as the seller.
2. **To promote digitalization of payments**
   AePS helps in doing more transactions through electronic means. It also helps in reducing the problems of cash transactions by enabling digital transactions.
3. **Ease of payments**
   Aadhaar system in AePS helps in making payments easier. Technological innovations always help to improve the payments scenario.
4. **Cashless Payments**
   AePS promotes cashless payments. Cashless payments provide convenience to customers and businesses to pay and receive money.
5. **Helps in collecting government initiated fund transfers**
   AePS helps in providing people social security pension, subsidies and other direct benefit transfers.

Basic requirements for AEPS

1. **IIN(Issuer Identification Number) of Bank**
   IIN is the Identifcation number of a bank. This is a unique 6 digit number. It is used by NPCI to verify the transactions.
2. **Aadhaar Number**
   Aadhaar number is the unique number given by Unique Identification Authority of India. It is a 12 digit number provided to people who have registered for Aadhaar Card.
3. **Fingerprint**
   Fingerprint should match with the Aadhaar at the time of enrollment with UIDAI. This biometric is unique and it is verified for making transactions using AePS.

Fig. 1: Requirements of AEPS

Working of AePS

Fig. 2: Working mechanism of AePS

For using AePS facility the Customer should link Aadhaar with the bank account. Let us know how AePS works. The Aadhaar holder initiates an authentication request by providing Aadhaar number to the authentication user agency using mobile phones, PCs or such other devices. Then Authentication agency transfers that to authentication service agency. Then the authentication service agency transfers that information to unique identification authority of india . This authority checks the data and transfers to Sub. Authorized user agency and they gives confirmation to authentication devices by verifying the customers fingerprint. After that the required service for customers is rendered. This is how the AePS works.

Membership of AePS

1. UIDAI has to duly approve the member bank to use authentication services.
2. Criteria for banks to join AePS :
   i) The bank which is the applicant should be a member of Type-A of Gross settlement system of RBI.
   ii) The bank which is the applicant should be eager to allocate to the NPCI's Settlement Guarantee Fund.
3. Sub-membership model of AePS can be utilised through:
   i) Banks who have Authentication User Agency's license but not RTGS membership
   ii) Banks who do not have Authentication User Agency's license.

Steps in AePS transactions

Fig. 3: Steps in AePS

Areas where AePS is used?

1. **India Post Payments bank(IPPB)**
   IPPB provides AePS enabled banking services like withdrawal of cash, depositing cash, Mini statement, Funds transfer using Aadhaar and other AePS facilities by NPCI.
2. **Banks**
   Banks provide AePS services for customers for doing various banking transactions.
3. **Insurance Companies**
   Insurance companies use AePS for providing insurance services.
4. **Stock Trading**
   Stock trading companies provide Stock trading services using AePS.
5. **Income Tax Return Filing**
   At present, for filing income tax returns it is mandatory to use AePS system.
6. **BHIM Aadhaar pay**
   BHIM Aadhaar Pay is the payment app used for doing commercial transactions in mobile phones for AePS transactions. It was launched on 14th April 2017. In the first phase the transaction limit was Rs. 2000 and now it has increased to Rs. 10000.

Merits of AePS

1. **Easier Payment of transactions**
   AePS helps in faster payments. Only thing we require is Banks IIN, Aadhaar number and fingerprint.
2. **Secured payment**
   AePS helps in making secured payment using biometrics scans. Biometric scanning verifies fingerprint. Frauds can be reduced by these types of verification.
3. **Promotes Financial Inclusion**
   Every transaction that is done in AePS keeps evidence in the form of transaction registry. So it helps in promoting financial inclusion.
4. **Safe disbursal of government schemes and direct benefit transfers(DBT)**
   It helps in safe and secured disbursal of all government schemes and DBTs.
5. **Cashless Payments**
   AePS provides cashless mode of payments. So it promotes cashless society.

Demerits of AePS

1. **Problems of biometric system**
   The main problem of this system is that it involves these types of failures. They are:
   (i) Denial of Service(DoS)
   DoS occurs when the system is not able to recognize the authorized user. This attack occurs when a hacker attacks this payment network.
   (ii) Intrusion
   It occurs when the system incorrectly recognizes a wrong user as the authorized user. This attack also occurs when a hacker hacks the network and breaks the loopholes in this network.
   (iii) Adversary Attack
   It is an attack where an adversary manipulates the biometrics. The adversary is an insider which directly handles the networks.

Role of different participants in Micro ATM Network

1. **Issuing Bank**
   This bank maintains the customer's record and all the details related to the customer in a Core banking system. The Aadhaar can be mapped for all transactions involving AePS.

2. **Acquiring Bank**
   This bank maintains relationship with business correspondents. It works as a facilitator for AePS transactions.
3. **Business Correspondent(BC)**
   He is designated by the bank, and gives access to fundamental banking services by utilizing the Micro ATM.
4. **Technology Service Provider(TSP)**
   It provides support to business correspondents by providing technology.
5. **Multilateral switch**
   It is used in OFF- US transactions which gives interoperability.
6. **UIDAI**
   It is the organisation which provides Aadhaar Card. It provides a 12 digit unique number. This is the Aadhaar number.
7. **IBA, IDRBT, NPCI, UIDAI**
   These bodies are the watchdog of Micro ATM standards.
8. **RBI**
   It controls over all payment systems in India including Micro ATM networks.

According to RBI's Report on High level Committee on Deepening of Digital Payments, there is rapid growth in the AePS from 2015 to 2019. Transactions size in 2014-15 was just 1.4 thousand. It has increased to 2.7 thousand in 2018-19. These innovations help users who belong to remote areas to access bank accounts easily. At present the transactions in AePS rose to 80 million users.

New Policies by RBI for AePS

Banks should pay penalty for failed transactions

Recently in Reserve Bank of India 's Monetary Policy statement which was published on April 4, 2019, RBI has proposed to make a structure on Turn Around Time (TAT) which was made on the basis of consumer complaints regarding failed transactions . As per RBI, the failed transactions include various factors which may not be directly related to the consumer. It might be on account of various aspects that are not directly related to the consumers like interruption of links in communication, lack of money in ATMs, break in sessions, non-credit to recipient's record because of different causes etc. Rectify / Compensate the amount that is paid to the customer for these failed transactions isn't uniform.

According to Retail Payments Statistics by NPCI on September 2019, AePS transactions have increased rapidly in the financial year 2019-2020. Doing transactions in AePS is easy. Transactions are done on the basis of biometrics. It is highly secured. So people are more interested to do transactions using AePS.

Recent AePS enabled Apps

1. **Paisa Nikaal App**
This app uses AePS system to withdraw, deposit and transfer cash. It can also be used to check bank statements without visiting any branch. IMPS method is used to transfer money to bank account.
2. **eDigital AePS**
This app uses multiple platforms for payment. It uses AePS , Immediate Payment Service, Bharat Bill Payment System etc.

Criticisms against AePS

1. **AePS needs only fingerprint and Aadhaar number to withdraw money**
Many experts are of the view that AePS authentication is vulnerable to attacks. Biometric authentication should be modified from fingerprints and Aadhaar number to face recognition and retina scans.
2. **OTP or PIN is not required for AePS transactions**
One Time Password(OTP) or Personal Identification Number(PIN) is used in all card based transactions. But in AePS transactions these type of authentications are not required. So it becomes a serious threat to people who are using AePS mode of payments.
3. **Two factor authentication should be maintained**
Two factor authentications should be made for AePS transactions. Bypassing of two factor authentication becomes very difficult.

Covid-19's Impact on AePS

According to World Health Organization" Coronavirus disease (COVID-19) is an infectious disease caused by a newly discovered coronavirus. COVID-19 virus spreads primarily through droplets of saliva or discharge from the nose when an infected person coughs or sneezes." This virus emerged in China and started spreading in India at the end of January 2020. India was under lockdown for around 2.5 months. Business organisations, educational institutions, tourism, manufacturing firms, private companies and some of the government institutions were under lockdown. This pandemic has created significant impact on digitization of payments. ATM counters were avoided by majority of people to avoid contacts with infected persons. Contactless payment method got more importance. AePS showed 20 to 25 % growth in transactions. Postal department is also providing AePS services to their customers. So customers can use their accounts using AePS while staying at home. Direct Benefit Transfers were given to people using AePS. According to the finance ministry, AePS transactions were doubled to 11.3 million during this pandemic period. (Hindustan Times, May 2020)

Conclusion

AePS has helped to make Aadhaar as a primary identification and helped in making payments and accepting payments. Compared to other services offered by NPCI, AePS is easier and secured because of IIN, Aadhaar number and fingerprint. After demonetization, BHIM (Bharat Interface for Money) has been launched. BHIM is also an online payment method which uses Unified Payment Interface for doing different kinds of transactions. The difference comes in the process of authentication. BHIM uses UPI and Aadhaar Pay uses biometric verification. It is highly secured. Government has launched Aadhaar Pay to avoid the problems of BHIM. As per the current statistics given by NPCI for the year 2019-20 AePS transactions have increased tremendously compared to BHIM.

This payment mode will be used more in coming years. Now people are more interested in faster payments due to the technological developments. The merchants are trying to provide AePS because they will get additional benefits. For bankers AePS based mode of transactions is very cheap and it will also help the people who are under banked. Public Sector banks like SBI and other private banks are also promoting AePS in rural areas. In rural areas, the number of banks and ATMs are very few in number. DBT is done by the government through Aadhaar. Only Aadhaar card and bank account is needed to do this. So these all things will promote AePS in rural areas.

Day by day AePS based transactions is getting more popular. With further innovations and developments in technologies AePS will be used in all modes of payments. This may compete with other modes of payment and may be widely accepted internationally. AePS based transactions may become the first priority among the common man in the years to come.

Novel Graph-Based Approach for Creating and Comparing Music Arrangements

Szymon MUSZYNSKI

Military University of Technology in Warsaw, Poland
S. Kaliskiego Str. 2, 00-908 Warsaw, Poland
szymon.muszynski@wat.edu.pl

Abstract

This article provides a brief summary on graph and network-based models of melody. It describes how to use these models for arrangement generation and how to compare results obtained with different generation methods. The comparison may be based on characteristics of a graph representing an original piece and graphs of generated arrangements.

Two main goals of this article are: to provide a formal description of existing models and generation methods in terms of stochastic processes and to introduce the new methods of comparing musical tracks using their graph representation.

Keywords: graph theory, Markov chains, automated music arrangement, musical pieces comparison

Introduction

Computer Science has already made a significant impact on almost any other branch of science. It also changes the contemporary styles in music. Development of mathematical models and computer software inevitably impacts musician's life – not only in terms of listening to music. People use mobile devices to tune instruments. Many composers prefer computer-pluggable instruments combined with score writing software to traditional instruments and paper scores to create new arrangements. Moreover, computer-generated music arrangement is also a rapidly growing field of research.

Many computer-driven arrangement methods have been developed so far. For instance, there are models using neural networks (Liu, H. and Yang, Y. (2018), 'Lead sheet generation and arrangement by conditional generative adversarial network,' International Conference on Machine Learning and Applications, ISBN: 978-1-5386-6805-4, 17-20 December 2018, Orlando, USA, 722-727.), genetic algorithms (Daylamani, Z., Araabi, B. N. and Lucas, C. (2006), 'A novel approach to automatic music composing: using genetic algorithm,' *International Computer Music Conference Proceedings (ICMC),* 2006, 551-555.) and many others (e.g. Huang, J.-L., Chiu, S.-C. and Shan, M.-K. (2012), 'Towards an automatic music arrangement framework using score reduction,' *ACM Transactions on Multimedia Computing*, *Communications*, *and Applications,* 8, 8:1-8:23. or Smith, R., Dennis, A. and Ventura, D. (2012), 'Automatic composition from non-musical inspiration sources,' Proceedings of the Third International Conference on Computational Creativity (ICCC), ISBN 978-1-905254668, 30 May-1 June 2012, Dublin, Ireland, 160-164.).

Among others, graph-based music arrangement also gives good results in terms of generated music *hearability* (this term is used in the article of Yang, C., Tse, C. K. and Liu, X. (2009), 'Analyzing and composing music from network motifs,' International Symposium on Nonlinear Theory and Its Applications (NOLTA), ISBN: 978-4-88552-241-3, 19-21 October 2009, Sapporo, Japan, 407-410.). Arrangement is created using an original song.

The main purpose of this article is to summarize common methods of creating graph-based representation of sheet music and arrangements – with formalization of methods that were previously described only in a descriptive way. The article also proposes new methods of music comparison.

The article consists of seven chapters. The first one is an introduction. Chapter two is a summary of how to present notes as a graph vertices. Chapter three describes differences between graph and network models of melody. Chapter four provides a description of methods of generating an arrangement from graph/network structures in terms of

Markov chains. Chapters five and six describe different approaches to measure track similarity: graph-structure-based and text-based accordingly. Chapter seven is a summary of the article with ideas for further research.

Mapping notes to vertices

Music used for arrangement generation methods described in this article is restricted to note frequencies having an exact representation in the equal temperament (so that they can be written in the sheet music) and being hearable by human ear. Also, it is restricted to monophony – there is only one tone played in every single moment of time. In fact, many instruments do not have possibility to play more tones at a time (e.g. human voice, most wind and brass instruments). For all the chord instruments, we may split notes from existing chords into separate tracks – so that we do not lose any information from the original piece.

Figure 1: Example of splitting polyphony to multiple monophonic tracks

In Figure 1 we can see that every note in the resulting piece is preceded by exactly one note (except the first one) and precedes exactly one note (except the last one). This assumption allows to use graph/network models.

Consider the following formal representation of the graph (described similarly to Korzan, B. (1978), Elementy teorii grafów i sieci. Metody i zastosowania, Wydawnictwo Naukowo-Techniczne, Warsaw.):

$$G = \langle V, E, P \rangle \tag{0.1}$$

where:
V – set of graph vertices,
E – set of graph edges,
$P \subset V \times E \times V$ – relation such that:

1) $\forall e \in E \, \exists v_1, v_2 \in V : \langle v_1, e, v_2 \rangle \in P$

2) $\left[\langle v_1, e, v_2 \rangle \in P \wedge \langle x_1, e, x_2 \rangle \in P \right] \Rightarrow \left[(v_1 = x_1 \wedge v_2 = x_2) \vee (v_1 = x_2 \wedge v_2 = x_1) \right]$

Let $N = \{N_1, \cdots, N_L\}$ be a set of all notes in a track.
Consider the following formal representation of a single note:

$$\mathrm{N}_i = \langle \mathrm{freq}_i, \ \mathrm{m}_i, \ \mathrm{t}_i \rangle, \quad i = 1, \ldots, L \tag{0.2}$$

where:
freq_i – frequency of the i-th note ($\mathrm{freq}_i \in [16{,}16000] \cup \{-1\}$ – -1 is used as a representation of a rest),
m_i – duration of the i-th note (e.g. in seconds or as note length: half, quarter etc.),
t_i – moment in the track in which the i-th note starts (seconds from the beginning of a track or a measure number).

Notes from a single track may be represented as graph's vertices. There are a few ways for representing notes from the original piece and transform them to graph nodes. They will be further defined formally as functions:

$$f : N \to V \tag{0.3}$$

First, we may create one vertex for each "identical" note – i.e. having the same frequency and duration. Vertex name consists of three parts: note frequency, underscore sign, note duration. Alternatively, frequency may be replaced by note name for readability. This note representation is called full representation.

This method results in relatively big graphs: using all possible 121 note frequencies (12 notes in each of 10 octaves, 1 artificial frequency for rests) combined with 18 note lengths that are used commonly (whole, half, quarter, eighth, sixteenth, thirty-second – each can also be dotted and double-dotted) results in graph having up to 2178 vertices. The main advantage is preserving all important information in the graph – as shown in Figure 2.

Figure 2: Example of a network representing the track above with full representation of notes

Alternatively, each note having the same frequency (regardless of its duration) may be mapped to the same edge. This representation is called simplified representation.

Formula to calculate vertex' index in simplified notation is shown below.

$$f(freq_i) = \begin{cases} 121 & \text{freq}_i \le 0 \\ 12 * \log_2\left(\dfrac{\text{freq}_i}{440\,Hz}\right) + 58 & \text{freq}_i > 0 \end{cases} \tag{0.4}$$

Values below 0 are used as rest representation. Values above 0 are other notes' frequencies (with $A_4 = 440$ Hz being 58th human-hearable note in the equal temperament).

Such a graph is much smaller (with a maximum of 121 vertices) but some vital piece of an information from the original song is being lost - as shown in Figure 3.

Figure 3. Example of a network representing the track above with simplified representation of notes

We may also "flatten" notes just to their key signature (without an octave name). Thus, this representation is called simple representation. Formula to calculate vertex index in simple representation is shown below:

$$f(freq_i) = \begin{cases} 12 & \text{freq}_i \le 0 \\ \left[12 * \log_2\left(\dfrac{\text{freq}_i}{440\,Hz}\right) + 58\right] mod\, 12 & \text{freq}_i > 0 \end{cases} \tag{0.5}$$

Usage of this representation causes losing an information about notes' frequency and length. However, this type of mapping is more human-readable as graphs are relatively small (there are maximum 13 vertices). An example of such a graph is shown in Figure 4.

Figure 4. Example of a network representing the track above with simple representation of notes

The next topic – creating edges in a music graph is covered in the next chapter.

1. Reflecting note precedence as edges

The second important part of creating graph or network from the sheet music is: how to reflect "connections" between notes.

Important part of modelling sheet music as a graph is a precedence relation. It can be described formally as:

$$R = \{\langle N_1,\ N_2\rangle \in N \times N : t_1 \le t_2\} \tag{3.1}$$

where:

$N_i,\ t_i$ – as defined in (0.2)

N – set of all notes in a track.

Relation between notes in the track defined as above is:

1. connex:

$$\langle N_1, N_2\rangle \in R \vee \langle N_1, N_2\rangle \in R \tag{3.2}$$

2. reflexive:

$$\langle N_1, N_1\rangle \in R \tag{3.3}$$

3. transitive:

$$[\langle N_1, N_2\rangle \in R \wedge \langle N_2, N_3\rangle \in R] \Rightarrow \langle N_1, N_3\rangle \in R \tag{3.4}$$

4. antisymmetric:

$$[\langle N_1, N_2\rangle \in R \wedge \langle N_2, N_1\rangle \in R] \Rightarrow N_1 = N_2 \tag{3.5}$$

Thus, such a relation is a linear order on the set of notes.

If we create a rank over this set of notes with its linear order (as described by Ameljańczyk, A. (2013), 'Metoda podziału zbioru obiektów na wielokryterialne klastry jakościowe,' *Biuletyn Instytutu Systemów Informatycznych WAT,* 12, 1-7.), we may start modelling connections between pairs of notes according to their "immediate precedence". Such pairs may be described formally as:

$$I = \{\langle N_1, N_2\rangle \in R : t_2 = t_1 + m_1\} \tag{3.6}$$

where N_i, t_i, m_i are described in (0.2) and $R \subset N \times N$ is described in (3.1).

Several possibilities exist to model the precedence relation in a graph or network. The following section will summarize ways to create edge structure from the track.

The first one is to create an edge for each unique precedence between notes corresponding to vertices. This means that we create an edge for the first occurrence of that precedence – but every subsequent precedence of notes mapped to these vertices will not change the graph structure. Thus, we create an *unigraph* (a.k.a. simple graph – where multiple edges between a pair of nodes are not allowed).

This method simplifies the structure and produces a summary of connections between notes from the track. Of course, an information about a cardinality of each vertex pair's precedence is lost – as shown in Figure 5.

Figure 5. Example of an unigraph representing the track above. Multiple occurrence of the precedence between notes c and d is ignored

The second way of modelling the precedence is to use a *multigraph* (where multiple edges between a pair of nodes are allowed). Therefore we may restore the cardinality of precedence between notes from a track by counting all the edges between nodes corresponding to these notes – as shown in Figure 6. Unfortunately, this method results in graphs with many edges for long pieces (i.e. having many notes). Therefore, many publications (such as Liu, X., Tse, C. K. and Small, M. (2009), 'Composing music with complex networks,' International Conference on Complex Sciences: Theory and Applications (COMPLEX2009), ISBN: 978-3-642-02466-5, 23-25 February 2009, Shanghai, China, 2196-2205.) ignore this method as there exists less memory-exhaustive approach: using the network.

Figure 6. Example of a multigraph representing a track above. Multiple occurrence of the precedence of notes c before d results in two edges between the corresponding vertices

The third method of modelling the precedence relation is to use a network (weighted graph). Just as in the previous method, we don't ignore multiple occurrence of a precedence between the notes but, unlike multigraph, we increment a weight of an edge instead of creating a new one – as shown in Figure 7.

This method allows to restore the cardinality of precedence between each pair of nodes and produces more readable and more concise structure.

Figure 7. Example of a network representing a track above. Multiple occurrence of the precedence of notes c before d results in a single edge with a weight of 2 between corresponding vertices

The last decision to be made is: should we use directed edges (arcs) or undirected (lines)?

In the first method we create an arc from the first note from pair. Therefore, resulting *digraph* (directed graph) shown in Figure 8 contain arcs only in such directions that exist in the original piece. We do not ignore the order in each pair from the precedence relation.

Figure 8. Example of a digraph representing a track above. Occurrence of the precedence between notes c and d (and back) results in two arcs between vertices – one in both directions

When we use arcs with network, we can calculate weight for an arc from v_k to v_l as cardinality of an immediate precedence of note N_i before N_j such that:

$$\langle N_i, N_j \rangle \in I \tag{3.7}$$

$$\langle f(N_i), e, f(N_j) \rangle = \langle v_k, e, v_l \rangle \in P \tag{3.8}$$

where I is defined in (3.6), v, e, P are defined in (0.1) and $f(N_i) = v_k$ was described in (0.3).

The second approach is to use an undirected graph. In this scenario we create a line between edges regardless of which note from pair occurs first in the track. When there is a precedence between two notes corresponding to vertices A and B and then two another notes corresponding to vertices B and A (i.e. there should be two arcs between them in a digraph), we use a single line instead. Thus, the graph in Figure 9 informs only about "notes' neighborhood" in the track but not strictly about the precedence.

Figure 9. Example of an undirected graph representing a track above. Occurrence of the precedence between notes c and d (and back) results in a single edge between vertices corresponding to them

When we use this approach for networks, then the weight of each line between vertices v_k and v_l is a cardinality of an immediate precedence of a note N_i before N_j or vice versa such that:

$$\langle N_i, N_j \rangle \in I \vee \langle N_j, N_i \rangle \in I \tag{3.9}$$

and

$$\langle f(N_i), e, f(N_j) \rangle \in P \vee \langle f(N_j), e, f(N_i) \rangle \in P \tag{3.10}$$

where all symbols have the same meaning as in (3.8).

For both formulae (3.8) and (3.10) we may calculate a weight of each vertex as an aggregate weight of each outgoing arc or an incident line.

Both approaches described above must allow creating loops as there may occur multiple identical notes (with the same frequency and duration) one after another – as shown in figures 8 and 9.

Combination of all these aspects (type of chosen representation of notes, type of graph structure, type of used edges) affects resulting arrangement generated from the graph.

Creating arrangements from the graph

As graph model of an original piece is constructed, we may start generating arrangements.

To do so, we will use a random walk (or controlled random walk) algorithm on the graph. It is an example of a stochastic process – or strictly speaking: a Markov chain. In this case the set of graph nodes is the state space and the indices of arrangement notes are an index set. Both of them, of course, are discrete.

To fully characterize the process, we need to provide: the vector of initial distribution and the transition matrix. We may interpret the former as choosing the first note of an arrangement and the latter as choosing the following notes of the recomposed work. There are multiple methods of constructing them from the original song and the aim of this chapter is to provide a description of these methods.

We may construct an initial distribution vector in a multiple ways. First of them is to start the arrangement using a randomly chosen note from the prototype (vertices having a non-zero degree). Therefore, the initial probability for each vertex will be calculated from the following formula:

$$p_i(0) = \begin{cases} \dfrac{1}{\left|\left\{v_j \in V : \deg\left(v_j\right) > 0\right\}\right|}, & deg\left(v_i\right) > 0 \\ 0, & deg\left(v_i\right) = 0 \end{cases} \tag{3.11}$$

where $deg\left(v_i\right)$ is a degree of v_i vertex.

A non-zero degree condition is used to eliminate isolated vertices (corresponding to notes that aren't used in the original piece – as depicted in Figure 10).

$$p_0(1) = \frac{1}{2}$$
$$p_0(2) = \frac{1}{2}$$
$$p_0(3) = 0$$

Figure 10. A sample graph with the initial distribution calculated using the formula (3.11). Vertex indices are provided in square brackets

The second approach is to start an arrangement with the same note as in the original piece. In this scenario the following formula is used:

$$p_i(0) = \begin{cases} 1, & f(N_1) = v_i \\ 0, & f(N_1) \neq v_i \end{cases} \tag{3.12}$$

where $f(N_1)$ is defined in (0.3).

The third method is to begin the recomposed work with the most frequently used note from the original song (as depicted in Figure 11). If there is more than one such a note, we choose one of them randomly. The following formula applies:

$$p_i(0) = \begin{cases} \dfrac{1}{\left|\left\{v_j \in V : \deg\left(v_j\right) = \Delta(G)\right\}\right|}, & deg\left(v_i\right) = \Delta(G) \\ 0, & deg\left(v_i\right) < \Delta(G) \end{cases} \tag{3.13}$$

where $\Delta\left(G\right) = \max\limits_{v \in V} deg\left(v\right)$ is a graph's degree.

$$\Delta\left(G\right) = 2 \qquad p_0(1) = 0 \quad p_0(2) = 1 \quad p_0(3) = 0$$

Figure 11. A sample graph with the initial distribution calculated using the formula (3.13). Vertex indices are provided in square brackets

The fourth method is to draw an initial vertex with a probability according to its degree in the graph. The following formula is used in this case:

$$p_i(0) = \frac{\deg(v_i)}{\sum_{v_j \in V} \deg(v_j)} \tag{3.14}$$

Therefore, the more frequent was the note used in the original piece, the bigger is the probability to draw it as the first note of an arrangement.

Two additional methods may be used for networks. First of them is to choose the vertex corresponding to the most frequently used note from the prototype (or, if there are more of them, a randomly chosen one). The weight of a vertex $\xi(v_i)$ is used in the formula:

$$p_i(0) = \begin{cases} \dfrac{1}{\left|\{v_j \in V : \xi(v_j) = \max \xi(v)\}\right|}, & \xi(v_i) = \max\limits_{v \in V} \xi(v) \\ 0, & \xi(v_i) < \max\limits_{v \in V} \xi(v) \end{cases} \tag{3.15}$$

where $\xi(v_i)$ is calculated as described under (3.10).

The second additional approach for networks is to draw a starting vertex accordingly to degrees of all vertices. The following formula is used in this case:

$$p_i(0) = \frac{\xi(v_i)}{\sum_{v_j \in V} \xi(v_j)} \tag{3.16}$$

where $\xi(v_i)$ is described as before.

In this approach a note which is used more frequently in an original part has also a bigger probability to begin the arrangement (just as in the fourth method described in this section).

The second part of the random walk is a method of choosing the following vertices. It is similar to choosing the first vertex, although the main difference is considering only successors of the current vertex (instead of all the vertices of the graph).

Due to this similarity, formulae to calculate values in the transition matrix are also somewhat similar – each row of this matrix is calculated just as described above with the main difference: $v_j \in V$ is replaced with $v_j \in \Gamma(v_x)$, where $\Gamma(v) = \{u \in V : \exists e \in E \langle v, e, u \rangle \in P\}$ is a set of successors of the vertex v (current vertex).

The first method of choosing the next vertex is to choose the neighbour of the current vertex v_x having maximum degree (or, when there are many such vertices, one of them randomly). This leads to the following formula:

$$p_{xj} = \begin{cases} \dfrac{1}{\left|\left\{v_i \in \Gamma(v_x) : deg(v_i) = \max\limits_{v \in \Gamma(v_x)} deg(v)\right\}\right|}, & v_j \in \Gamma(v_x) \wedge deg(v_i) = \max\limits_{v \in \Gamma(v_x)} deg(v) \\ 0 & otherwise \end{cases} \tag{3.17}$$

In this scenario we eliminate notes poorly connected with other notes. This may be considered a disadvantage since notes having a low degree may still appear frequently.

The second method of choosing the next vertex is to simply draw it from the neighbours of the current vertex. This may be expressed with a formula as follows:

$$p_{xj} = \begin{cases} \dfrac{1}{\left|\{v_i \in \Gamma(v_x)\}\right|}, & v_j \in \Gamma(v_x), \left|\Gamma(v_x)\right| > 0 \\ 0 & otherwise \end{cases} \tag{3.18}$$

This leads to a *pure random walk*. Its obvious consequence is that connections between notes may occur more frequently than in the original piece.

Two additional approaches are possible when walking the network. First of them is drawing the vertices proportionally to their weights ($\xi(v)$ – vertex weights describe how many times this note appeared in the original piece). The more often it was used in the track, the bigger is the probability of choosing it as the next visited vertex. This may be described formally as:

$$p_{xj} = \begin{cases} \dfrac{\xi(v_j)}{\sum_{v_i \in \Gamma(v_x)} \xi(v_i)}, & v_j \in \Gamma(v_x), \left|\Gamma(v_x)\right| > 0, \xi(v_i) > 0 \\ 0 & otherwise \end{cases} \tag{3.19}$$

Normally, this leads to the note distribution more similar to the original piece than in previously described methods.

The last method described in this article is strongly inspired by connections from the prototype. This is achieved by choosing the vertices accordingly to weights on their edges (ψ) which results in the following formula:

$$p_{xj} = \begin{cases} \dfrac{\psi(e_k)}{\sum_{e_i \in E'(x)} \psi(e_i)}, & \langle v_x, e_k, v_j \rangle \in P \\ 0 & otherwise \end{cases} \tag{3.20}$$

where v_i, e_j, P - described in (0.1).

The biggest advantage of this method is preserving an overall style of the original piece. Since this method uses *controlled random walk*, it produces results with greater similarity to the prototype than the other methods. The comparison of results produced by a selection of these methods is described by Liu, X., Tse, C. K. and Small, M. (2009), 'Composing music with complex networks,' International Conference on Complex Sciences: Theory and Applications (COMPLEX2009), ISBN: 978-3-642-02466-5, 23-25 February 2009, Shanghai, China, 2196-2205..

In addition to methods described in this chapter there is a variety of other methods of walking the graph. Due to article length limitations they will not be described here – but most of them result in a *hearability* better than achieved with *pure random walk* and worse than the *controlled random walk* methods described above.

It should be mentioned that there is an issue with generating the note from the vertex (i.e. applying the inverse function $f^{-1}: V \to N$ – see (0.3)) when simple or simplified note representation was used in the graph. In such cases we need to determine: the octave and duration or just a duration, respectively. The easiest way is to simply draw them – but this may lead to poor *hearability* of the generated arrangement and lower similarity of the graph representations of both pieces.

Last but not least, one more issue needs to be mentioned. Although the stochastic process' realizations may be of infinite length, the generated arrangements must be finite (in terms of note count and duration). Intuitively it is a common practice to generate a recomposed work similar to the prototype – i.e. having the same note count or the same duration (same count of bars). The former arrangement tends to be easily compared with the original piece – networks representing both pieces have the same accumulated edge weight. The latter leads to obtaining a more similar sheet music.

Comparing arrangements and different musical pieces: structure-based approach

In addition to the music generation itself, we can also compare generated arrangements using created graphs. Music comparison can depend on multiple metrics of the network or may use path representation of melody.

Having the graph structure built with any method described in the previous chapters, we can compare pieces using graph/network metrics instead of comparing tracks themselves. Therefore, we can define a vector of graph metrics consisting of values as follows:

- vertex count,
- edge count,
- graph density,
- graph diameter,
- assortativity,
- global clustering coefficient,

- mean vertex degree,
- mean vertex distance,
- mean vertex betweenness,
- other values (whenever applicable).

We can measure the similarity of arrangements or different musical pieces by comparing values of this vector. Such a comparison in a smaller space (i.e. vectors having less dimensions) was proposed by Liu, X., Tse, C. K. and Small, M. (2009), 'Composing music with complex networks,' International Conference on Complex Sciences: Theory and Applications (COMPLEX2009), ISBN: 978-3-642-02466-5, 23-25 February 2009, Shanghai, China, 2196-2205.. Unfortunately, such an approach is not precise; we have to compare dimensions one by one. At the same time, we must keep in mind the possible range of each of these dimensions (since, for example, the domains of vertex count and graph density differ significantly).

The aforementioned comparison method has many practical disadvantages. It would be better to compare one single value describing a distance between musical pieces instead of vectors. This leads to an improved method of comparison involving calculation of the vector norm:

$$\|x - y\|_p = \left(\sum_{n=1}^{N} \left(|x_n - y_n|\right)^p\right)^{1/p}, p \geq 1 \qquad (3.21)$$

where x_n and y_n is the n-th dimension of the vector describing the graph representation of the compared pieces x and y accordingly.

Such a measure of similarity is much easier to comprehend, interpret and use. Especially when all values of the input vectors are normalized (this is possible since all the values, including vertex and edge count are bounded by the definition of the problem), the distance between musical pieces may vary only from 0 to $\sqrt{2}$. Using a single, bounded value for measuring a distance between musical pieces results in easier comparison.

Such a comparison can be made both on arrangements coming from the same original song and on separate musical pieces. Comparing two tracks having the same origin can be also made using concepts from multi-objective optimization, especially a definition of the ideal point.

Instead of comparing musical pieces by measuring the distance between them (as we do for separate pieces), we can define the original piece as an ideal point. Then arrangements may be compared by calculating their distance to this ideal point (their "innovativeness"):

$$R_p^{\overset{*}{y}}(y) = \left\|\overset{*}{y} - y\right\|_p = \left(\sum_{n=1}^{N} \left(\left|\overset{*}{y}_n - y_n\right|\right)^p\right)^{1/p}, p \geq 1 \qquad (3.22)$$

where $\overset{*}{y}_n$ is the n-th dimension of the vector describing the graph representation of the original piece (being an ideal point) and y_n is the n-th dimension of the vector describing the graph representation of the compared arrangement.

What needs to be mentioned is: despite the fact that we use a concept from the multi-objective optimization, our goal is not to optimize the resulting arrangement. The ideal point is always an acceptable solution – so no optimization is necessary.
It is also worth mentioning that none of these methods allow to measure an aesthetic feeling associated with generated arrangements. This may be an additional area of research.

Comparing arrangements and different musical pieces: text-based approach

Alternatively, we can compare musical pieces as if they were two texts. Every note (represented as three to five symbols: mandatory note name consisting of a letter and optional flat/sharp sign, optional octave number, mandatory underscore for readability, mandatory duration – as in Figure 2 should be considered a single character. Then we may compare tracks using distance metrics just as defined for strings (e.g. Hamming, Levenshtein or Damerau-Levenshtein distance).

The important difference between measuring an edit distance between "plain" strings and "note strings" is that each single note should be considered a single symbol (regardless of how many characters it is internally composed). Formally the "note-Hamming" distance may be described as:

$$DH(a,b)=\sum_{i=1}^{L}\left[N_i \neq N_j\right] \tag{3.23}$$

where a,b – tracks of length L and $\left[N_i \neq N_j\right]$ is the "Iverson bracket" returning 0 if notes N_i, N_j (defined in (0.2)) are equal and 1 otherwise.

Similarly, "note-Levenshtein" distance may be calculated as $DL_{a,b}(|a|,|b|)$ with the following formula:

$$DL_{a,b}(i,j)=\begin{cases} \max(i,j), & \min(i,j)=0 \\ \min\begin{cases} DL_{a,b}(i-1,j)+1 \\ DL_{a,b}(i,j-1)+1 \\ DL_{a,b}(i-1,j-1)+\left[N_i \neq N_j\right] \end{cases} & otherwise \end{cases} \tag{3.24}$$

where $a,b,\left[N_i \neq N_j\right]$ described as in (3.23) but tracks may differ in length.

Therefore, the "note-Levenshtein" distance between c^1_⅛ and c^2_¼ is 1 – as they are single different notes. The "classical" Levenshtein or Hamming distance between strings mentioned above would be 2 – as there are 2 substitutions to be made. This difference is illustrated in Figure 12. All further references to these metrics mean their "note-oriented" interpretations (unless explicitly stated otherwise).

Hamming/Levenshtein (note-oriented):

Track1	c ¼	f ⅛	g ⅛	c^1 ½
Track2	d ¼	f# ¼	g ¼	b ¼
Change type	edit (different tone)	edit (different tone and duration)	edit (different duration)	edit (different tone and duration)

Overall distance: 4 (4 edits)

Hamming (classical):

Track1	c	_	¼	f		⅛	g		⅛	c	1	_	½
Track2	d	_	¼	f	#	_	¼	g	_	¼	b	_	¼
Type	e				e	e	e	e	e	e	e		e

Overall distance: 9 (9 edits)

Levenshtein (classical):

Track1	c	_	¼	f		_	⅛	g	_	⅛	c	1	_	½
Track2	d	_	¼	f	#	_	¼	g	_	¼	b		_	¼
Type	e				a		e			e	e	d		e

Overall distance: 7 (5 edits, 1 addition, 1 deletion)

Figure 12: Comparison between "note-oriented" definitions of Hamming or Levenshtein distance and their "classical" equivalents

Usage of Hamming distance to calculate the distance between tracks is very limited as it can be used only for strings of the same length. Tracks with identical count of participating notes occur rarely in the real-world examples, so this metric can only be used for short samples (comparison of a few bars from the original part – as in Figure 13) or when we generate arrangements having the same note count as the prototype.

Figure 13: Two same-length tracks compared with Hamming and Levenshtein distance = 1

It is worth mentioning that some operations which are allowed for "plain" strings are treated differently for their music equivalents according to the rules of the music theory. For example, deleting a single character (without modifying its neighbourhood) is allowed in text strings but we cannot simply delete a note existing in the middle of the track. Instead we must either replace it with a pause of the same length (which turns it to a modification instead of a deletion) or additionally adjust the duration of the preceding/following note (which increments the distance value by 2). The aforementioned examples are shown in Figure 14.

Figure 14: Two tracks compared with Levenshtein distance = 5. Hamming distance cannot be measured as tracks differ in length

Alternatively, we may use Damerau-Levenshtein distance which treats swapping elements as a single operation (as shown in Figure 15). Additionally, we can make further extension for these metrics and add separate weights for different operations. For example, changing a note duration may be considered a smaller change in the track than changing its octave (which in turn is smaller than changing its note name). The latter change may result in more chaotic track (or may break the harmony rules) – so such changes should be treated in a different manner and thus result in a greater distance.

Figure 15. Two same-length tracks compared with Damerau-Levenshtein distance = 1 (swapping of note g and rest is considered a single change)

Such methods may be used as described above for comparing multiple arrangements of the same musical piece. Whenever we create tracks similar to an original piece (i.e. tracks being compared are created using the same graph), we can use the aforementioned methods as-is, without additional changes.

If there is a need to compare different musical pieces, these methods need some additional improvements to be more sensitive. First of all, we should first standardize both compared pieces to the same key – or at least transpose one of them so they both use the same note name for a node with the highest degree. This pre-processing is necessary when we want to detect plagiarism. Otherwise of someone just changed the pitch, the resulting piece would not be considered a copy at all – as shown in Figure 16. In this case, the "Iverson bracket" used in (3.23) and (3.24) returns 1 since notes being compared are different $\left(freq_i \neq freq_j \right)$.

Figure 16. Two tracks using the same scale steps yet different pitches. The transposed track is considered a completely different piece without a standardization

Further pre-processing should be made for note durations. As long as we treat different note durations as being different symbols in the comparison (formally, the "Iverson bracket" used in (3.23) and (3.24) returns 1 since notes differ: $m_i \neq m_j$), the change of all notes' durations (e.g. dividing them by two: changing halves to quarters, quarters to eights etc.) will cause an algorithm to fail finding the plagiarism – though it would still be quite easy to see by a human - Figure 17 being an example. Therefore, we need to standardize note durations – for example we can change the longest duration existing in the piece to a full note (and multiply all the other durations consequently).

Figure 17. Two tracks using the same scale steps and pitches yet different note durations. The shortened track is considered a completely different piece without a standardization

Moreover, we can combine these text-based methods with simpler methods of note representation. Using them for the arrangement generation may indeed result in worse *hearability* of the resulting pieces – but on this particular field of application it may lead to more general comparisons (i.e. just comparing a tonal similarity without considering rhythmical motives used in both tracks). Such a generalization also results in a simpler preprocessing (note duration is not persisted in this representation so this part can be omitted causing no differences in the result).

Alternatively, we may also use other text metrics to describe a similarity of two tracks. Returning the length of the longest common substring (the longest motif existing in both pieces or copied from one piece to another one) is an example of such a measure.

Such a family of methods of measuring musical pieces distance may have a wide range of applications. First of all, it can be used for plagiarism control purposes – as an auxiliary method combined with currently used methods or an independent one. Alternatively, we can compare musical pieces from different genres or different authors to find the common part between them.

Summary

In this article the author described the current state-of-the-art in graph-based automatic music generation. He provided more formal description of previously existing methods of graph creation and music arrangement generation. He also proposed new methods of music comparison.

Generating an arrangement from the graph or network representing an original piece has many benefits. First of all, the recomposed work is somehow similar to the prototype since it is based on harmony used in an original. Therefore,

listener may easily recognize motifs from the original work. On the other hand, each arrangement differs a lot from the prototype since it uses connections between notes without the "context" of the whole motif.

Such a method of generating music may have various applications. For example, the music for movies or TV series may be easily created from a few motifs. Also, the polynomial complexity of proposed algorithms allows using them in real-time systems such as video games. Arrangements may be generated *a vista*, during the game.

One of the biggest limitations of existing graph-based generation methods is the requirement to have a maximum of one note at a time. This narrows the possibility of practical use of the current methods.

For now, we can use these methods for creating new motifs from the original piece (as well as a corpus of motifs) – but all the harmonization or orchestration must be made by an arranger in a traditional way.

Certainly, this is still poorly explored area of research. At least the following things need to be made: comparison of the described methods (using the graph representation of sheet music), improving *hearability* of arrangements generated with these methods. An attempt to generate music from polyphonic tracks must also be made to improve application possibilities.

This article provides some various attempts to define methods of comparing musical pieces by comparing a single value attached to them. This results in simplifying comparisons – as they no longer need to be made directly on sheet music or vectors of network characteristics. This also simplifies an interpretation of the outcome and gives a possibility to use them as auxiliary methods in different set of problems.

Simplification of the graph structure obtained with mapping music notes to graph vertices leads to worse *hearability* but it may result in better recognition of common musical motifs – as it allows to abstract from the details that are not significant in this comparison. Therefore, creating graphs either using full or simple note representation may be justified – depending on the purpose.

Methods of track comparison can be used for comparing different pieces as well as different arrangements of the same piece. After some pre-processing (which is necessary to standardize the compared tracks) they can even be used for automated plagiarism control.

Abstract

Recent and upcoming changes in health and safety regulations in railway networking affect railway transportation in ways previously unexplored. The need to maintain social distance, compulsory temperature checks, use of disinfectants and other safety measures, all introduce new hurdles for station management. It is in such cases when mindful interference in passenger movement across the station can increase the throughput and reduce delay-generated costs. In this paper we propose a way for modelling organized routing of passengers within a train station. The goal is to optimize trains' departure delays. We prove a crucial property of the model that greatly decreases its complexity and we show the connection of the passenger routing problem to the multi-flow commodity problem.

Keywords: Traffic Management, Social Distancing, Railway Station, Passenger Routing

Introduction

It has been made clear by Limin (2020), that the COVID-19 pandemic impacts public transportation in a severe and a negative way. Among others, Tardivo et al (2020) and Eurex report (2020) suggest that use of railway transportation could become more widespread as a viable alternative to other modes of public transportation should the latter fail to sufficiently adapt. Certain recommendations to increase the viability of railway passenger transportation have already been made. These include social distancing, hand hygiene, temperature testing and passenger screening (see Tirachini and Cats (2020), ECDC recommendations (2020)). These additional motions require time and effort to perform (and to enforce) which puts additional strain on the passenger routing infrastructure within a railway station. Additional effort has to be made to ensure that passenger movement within a railway station (especially in large railway stations) does not become the bottleneck of the railway infrastructure. This requires introducing new methods of coordinating passenger movement within railway stations.

Passenger movement prediction and routing within a train railway network is, following Qiao (2013) and Limin (2020), typically understood as routing between stations, trains and other modes of transportation. The routing is usually performed from the passengers' point of view, as in Dou (2013) or Yang (2013), but such personal preferences, while still observed and analysed (Kumar (2020)), need to be at least partially disregarded in times of crisis. Although there are also papers like Daamen (2005), Ahn (2017) that deal with the analysis and prediction of passenger movement inside of railway stations, none of them are aimed at passenger routing in a pandemic situation.

We postulate, that to battle the influence of the COVID-19 pandemic or any other widespread and contagious health hazard of the future, additional control tools have to be introduced. Like other public services, the railway applies suitable countermeasures listed by Yin (2020). In this paper we propose a method of coordinating passenger movement in a way that permits keeping social distance in movement between intermediate areas of the train station and the trains themselves. We propose that a series of gates, signs and human coordinators be used to guide

passenger movement in a way that ensures quick and safe boarding of a train and getting off of it. We formulate a decision making problem by modelling the movement within the station. The goal is to minimize train departure delays. We prove a crucial property of the formulation, one that greatly limits the number of decision variables and makes the problem significantly easier to solve.

Passenger Routing Model

We consider a flow network given as a directed graph **G**=(**V**,**E**) where **V**={1, 2, ..., V} is the set of (indexes of) nodes and **E**={1, 2, ..., E} is the set of (indexes of) arcs. The network represents the structure of the station, with nodes corresponding to passenger waiting areas, platforms and intermediate areas. Let the set of (indexes of) train runs served at the station be denoted as **R**={1, 2, …, R} where each train has $p_r \geq 0$ embarking passengers and $p_{r+R} \geq 0$ disembarking passengers. We assume that expected train arrival times are known and given as $t_r \geq 0$ while departure times $s_r \geq t_r$ are unknown and depend on how fast passengers embark and disembark. Projected arrival times t_r can differ from real ones w_r due to congestion. However we assume that $w_r \geq t_r$. We also assume that routes for embarking and disembarking passengers are separate (no upstream and downstream intermingling) to ensure that social distance is well maintained.

We model passenger movement as flows between nodes, where a_r, d_r are the arrival and destination nodes for passengers embarking train r while a_{r+R}, b_{r+R} are analogous for disembarking ones. Note, that it is easy to model multiple arrival nodes by making a_r a virtual node with outgoing high-capacity connections (likewise for destination nodes). We assume that trains with the same destination node (the same platform) have different projected arrival times $d_r = d_q \Rightarrow t_r \neq t_q$ and that they are served in order of projected arrivals. Flow capacity of each arc e, which is its ability to contain passengers in a single unit of time (ex. a minute), is constant, denoted as $c^e \geq 0$. We assume, that decisions about flow distribution are made with regards to specific time moments $z_h \geq 0$ where $h \in$ **H**={0, 1, 2, …, H}. We later show that the choice of H and z_h can be strictly limited without affecting the optimality of the solution. For simplicity of the notation we assume that $z_0=0$.

For each time period $m \in$ **M**={1, 2, …, M}, which is between two consecutive time moments z_{m-1}, z_m, a flow on arc e corresponding to train run r is given as $f_r^e(m) \geq 0$ for embarking passengers and as $f_{r+R}^e(m) \geq 0$ for disembarking ones. Furthermore, we denote as $p_r(m) \geq 0$ the portion of passengers that are served during time period m (embarking or disembarking, depending on the value of $r \in \tilde{\mathbf{R}}$={1, 2, …, 2R}). Let $b_r(m)=(p_r(m))/(z_m-z_{m-1})$ be the number of passengers embarking train r (or disembarking train R-r for r>R) in a single time unit.

This gives us the following constraints for the passenger routing problem.

$$\forall m \in \mathbf{M},\ \forall r \in \tilde{\mathbf{R}},\ \forall i \in \mathbf{V} \quad \sum_{j \in \mathbf{V}} f_r^{e=(i,j)}(m) - \sum_{j \in \mathbf{V}} f_r^{e=(j,i)}(m) = \begin{cases} 0 & a_r \neq i \neq d_r \\ 1 & i = a_r \\ -1 & i = d_r \end{cases}, \tag{1}$$

$$\forall m \in \mathbf{M}, \forall e \in \mathbf{E} \quad \sum_{r \in \tilde{\mathbf{R}}} f_r^e(m) b_r(m) \leq c^e, \tag{2}$$

$$\forall r \in \tilde{\mathbf{R}} \quad \sum_{m \in \mathbf{M}} p_r(m) = p_r, \tag{3}$$

$$\forall m \in \mathbf{M}, \forall r \in \tilde{\mathbf{R}}, \forall e \in \mathbf{E} \quad f_r^e(m) \geq 0, \tag{4}$$

$$\forall m \in \mathbf{M}, \forall r \in \tilde{\mathbf{R}} \quad p_r(m) \geq 0, \tag{5}$$

$$\forall r \in \mathbf{R}, \forall m \in \mathbf{M} \quad z_m < w_r \Rightarrow (p_r(m) = 0 \wedge p_{r+R}(m) = 0, \tag{6}$$

We calculate the departure times s_r the following way

$$\forall r \in \mathbf{R} \quad s_r = \min_{m \in \mathbf{M}: \sum_{n=1}^{m} p_r(n) = p_r \wedge \sum_{n=1}^{m} p_{r+R}(n) = p_{r+R}} z_m \tag{7}$$

and the real arrival times w_r the following way

$$\forall r \in \mathbf{R} \quad w_r = \max\{\max_{q \in \mathbf{R}: d_q = d_r, t_q < t_r} s_q, t_r\}. \tag{8}$$

For simplicity of notation, we define $s=\{s_1, s_2, \ldots, s_R\}$, $f = [f_r^e(m)]_{r\in\tilde{\mathbf{R}}, e\in\mathbf{E}, m\in\mathbf{M}}$ and $p = [p_r(m)]_{r\in\tilde{\mathbf{R}}, m\in\mathbf{M}}$. We optimize a nondecreasing function $Q(s)$ which represents the impact of delays on the quality of provided service and incurred costs. As such, assuming that $\mathbf{D}=\{(s, f, p) : (1)–(8)\}$, the optimization problem considered here can be defined as follows:

$$\min_{(s,f,p)\in\mathbf{D}} Q(s) \tag{9}$$

Model Analysis

First we note, that under fixed values of time moments z_h and fixed $p_r(m)$ the problem is reduced to a series of multi-flow commodity problems. Factually, the choice of z_h (and H) could vary, but we show that it can be limited to those time moments when trains arrive and trains depart. No additional time moments are going to improve the quality (or feasibility) of the solution. Consider two instances of the problem (9): Ω and $\tilde{\Omega}$. Let w_r, s_r be arrival and departure times for Ω and let $\tilde{w}_r, \tilde{s}_r$ be arrival and departure times for $\tilde{\Omega}$. $\mathbf{Z}=\{w_r: r\in\mathbf{R}\}\cup\{s_r: r\in\mathbf{R}\}$ and $\tilde{\mathbf{Z}}=\{\tilde{w}_r: r\in\mathbf{R}\}\cup\{\tilde{s}_r: r\in\mathbf{R}\}\cup\{\hat{z}_1, \hat{z}_2, \ldots, \hat{z}_N\}$ be the time moments for Ω and $\tilde{\Omega}$ respectively (we assume that $\hat{z}_i$ are different from one another and from $\tilde{w}_r$, $\tilde{s}_r$). Similarly, we denote feasible solution sets as $\mathbf{D}$ and $\tilde{\mathbf{D}}$ and solutions as (s^*, f^*, p^*) and $(\tilde{s}^*, \tilde{f}^*, \tilde{p}^*)$.

Theorem 1. If a feasible solution $(\tilde{s}, \tilde{f}, \tilde{p})$ to $\tilde{\Omega}$ exists, then a solution (s, f, p) to Ω also exists.

Proof. Let us construct (s, f, p). First we set $w_r=\tilde{w}_r$, $s_r=\tilde{s}_r$. This satisfies (8). We order $\tilde{w}_r$, $\tilde{s}_r$ in ascending order and denote them as $\hat{z}_h$. We order w_r, s_r in ascending order and denote them as z_h.

For each consecutive time period m of $[z_{m-1},z_m]$ we select $\tilde{m}$ so that $z_{m-1}=\hat{z}_{\tilde{m}-1}$. We consider each period m separately. If no $\hat{z}_i\in[z_{m-1}, z_m]$ then we take $f_r^e(m) = \tilde{f}_r^e(\tilde{m})$ and $p_r^e(m) = \tilde{p}_e^r(\tilde{m})$. Then constraints (1), (2), (4), (5) in Ω are satisfied directly from corresponding constraints in $\tilde{\Omega}$.

If some $\hat{z}_i\in[z_{m-1}, z_m]$ then, assuming there are $n+1$ of those they are as follows $\tilde{z}_{\tilde{m}} < \tilde{z}_{\tilde{m}+1} < \ldots < \tilde{z}_{\tilde{m}+n}$. We also know that $z_m = \tilde{z}_{\tilde{m}+n+1}$. Then we take $f_r^e(m) = \sum_{\tilde{n}=\tilde{m}}^{\tilde{m}+n+1} \tilde{f}_r^e(\tilde{n})\frac{\tilde{p}_r(\tilde{n})}{p_r(m)}$ and $p_r(m) = \sum_{\tilde{n}=\tilde{m}}^{\tilde{m}+n+1} \tilde{p}_r(\tilde{n})$.

Constraints (4), (5) are satisfied directly. For (1) from Ω we have

$$\forall r \in \tilde{\mathbf{R}}, \forall i \in \mathbf{V} \quad \sum_{j\in\mathbf{V}} f_r^{e=(i,j)}(m) - \sum_{j\in\mathbf{V}} f_r^{e=(j,i)}(m) = \sum_{j\in\mathbf{V}} \sum_{\tilde{n}=\tilde{m}}^{\tilde{m}+n+1} \tilde{f}_r^{e=(i,j)}(\tilde{n})\frac{\tilde{p}_r(\tilde{n})}{p_r(m)} - \sum_{j\in\mathbf{V}} \sum_{\tilde{n}=\tilde{m}}^{\tilde{m}+n+1} \tilde{f}_r^{e=(j,i)}(\tilde{n})\frac{\tilde{p}_r(\tilde{n})}{p_r(m)} =$$
$$= \sum_{j\in\mathbf{V}} \sum_{\tilde{n}=\tilde{m}}^{\tilde{m}+n+1} \frac{\tilde{p}_r(\tilde{n})}{p_r(m)}[\tilde{f}_r^{e=(i,j)}(\tilde{n}) - \tilde{f}_r^{e=(j,i)}(\tilde{n})] = \begin{cases} 0 & a_r \neq i \neq d_r \\ 1 & i = a_r \\ -1 & i = d_r \end{cases}. \tag{10}$$

From (2) for $\tilde{\Omega}$ let us note that

$$\forall e \in \mathbf{E} \quad \sum_{r\in\mathbf{R}} \sum_{\tilde{n}=\tilde{m}}^{\tilde{m}+n+1} \tilde{f}_r^e(\tilde{n})\tilde{p}_r(\tilde{n}) \leq c^e(z_m - z_{m-1}). \tag{11}$$

Then for constraint (2) from Ω we have $b_r(m)=p_r(m)/(z_m-z_{m-1})$ so

$$\forall e \in \mathbf{E} \quad \sum_{r\in\mathbf{R}} f_r^e(m)b_r(m) = \sum_{r\in\mathbf{R}} \sum_{\tilde{n}=\tilde{m}}^{\tilde{m}+n+1} \tilde{f}_r^e(\tilde{n})\frac{\tilde{p}_r(\tilde{n})}{p_r(m)}\frac{p_r(m)}{z_m - z_{m-1}} \leq c^e. \tag{12}$$

From our choice of $p_r(m)$, constraints (3), (6) and (7) are also satisfied.

Corollary 1. We also notice, that for a solution $(\tilde{s}^*, \tilde{f}^*, \tilde{p}^*)$ to $\tilde{\Omega}$ exists, then a solution (s^*, f^*, p^*) to Ω that satisfies $s^* = \tilde{s}^*$ also exists. In consequence $Q(s^*) = Q(\tilde{s}^*)$.

Presented properties of the problem make its size independent of the number of time units contained within the planning horizon, which in turn limits the number of decision variables as they are now bounded by $O(ER^2)$.

Conclusions and Further Work

In this paper we formulate a model for routing passengers within a railway station under rigid health and safety regulations aimed at limiting the progress of a pandemic. Formulated decision making problem consists of a series of interconnected multi-commodity flow problems but we show that the number of such problems to solve is limited by the number of trains. This property can be used in designing of a solution algorithm, as the relatively low number of decision variables makes the use of a solver a viable option for small-instanced problems. For larger instances of the problem, the possibility to use heuristic approach with the use of a genetic algorithm should be explored.

The modelling is done under the assumption of passenger rationality but irrational behaviours, not-unexpected under conditions of heightened stress, could be included in an expanded model. As could be train runs without a full passenger complement.

Abstract

Use of the official state language in the public sector and in the civil service in particular became one of the main requirements in the Baltic states after gaining their independence. The present paper argues that the further development of language policy within the civil service domain is a rational response to the existing language challenges. This argument is supported by the comparative analysis within the Baltic states experience. In this article, we reflect upon the role of world language practices and assessments on the detailed requirements to the language proficiency level of civil servants and discuss standards' design, implementation, and appropriation issues that will challenge the field over the next few decades.

Keywords*:* Baltic states, civil servants, communicative competence, standards-based assessment, titular language, language proficiency.

Introduction

This paper studies the evolution of the various levels of the quality assurance in the civil service and attempt to build language certification institutional system from the perspective of the existing opportunities for constructing its internal coherence, thus enhancing also its international dimension.

The objectives aim in this study consist in identifying the quality policies of the state language proficiency examination for civil servants and their implementation. We are attempting to offer an overview regarding the introduction and use of the language quality management instruments in public administration, as well as their convergence in Baltic states. The article argues that the language quality management can evolve due to using best language certification practices, which defines the overall direction of the process of building an elite corps of civil service. Being against the reluctance of the governmental institutions to alter the current format of the language certification, this process will inevitably lead to further convergence with approaches of international language certification centres. In this sense, internationalisation remains, perhaps, the only rational choice to meet the practical needs of the language policy in Baltic states.

The article consists of four parts accompanied by introduction and conclusion. Part 1 deal with language quality management in public administration. Part 2 provides the background on the study, focusing on the synergy of current language certification challenges and dominance of linguistic Russification. Part 3 provides insights into the policy formation and implementation process, revealing the drawbacks of the formal policy mode. Part 4 is devoted to the Baltic states experience, putting the need for synergy between the government and higher educational institutions at the core of the discussion. This part also provides case studies of practices within the language certification, implying that internationalisation is already an on-going process.

Quality assurance and language certification in public administration: theoretical approach

Spolsky (2009) defines language management as: "conscious and explicit efforts by language managers to control [language]choices" (p. 1) and as: "the explicit and observable effort by someone or some group that has or claims authority over the participants in the domain to modify their practices or beliefs" (p. 4). But in his book the terms "language management," "language policy" and "language planning" are used interchangeably.

Practice-oriented studies within the global organisation has focused on the communicative practices of language clustering and thin communication in relation to trans-organisational knowledge sharing and networks (Charles, 2006; Marschan-Piekkari et al., 1999a). From this point of view language management means that new speech varieties and repertoires are adopted to fulfil certain “lingua franca functions” (Blommaert, 2003, p. 609), which has implications for language users whose organisational position and influences will be determined by their awareness of such codes (Tange, 2009, p. 222).

It should be noted that language management changes organisational information and communication systems, and that improving to internal knowledge flows, enhancing public employees to use discretionary power for maximasing exchanges that request their use of official language.

The current study advances this stream of research by concentrating on managing language diversity and how diversity and dissimilarity measures affect public employees' attachment to employment in a multicultural public administration (Binderkrantz, 2011; Ritz, 2018)

Trying to incorporate the concept of Quality Management in our research it’s useful to concentrate on it features (Zurga, 2008; Matei, 2011, p. 69): main goal is to acquire customer satisfaction; quality is defined by the customer; influence on all activities of the organization; customers are external; it closes the activities of control, but primarily involves the management of the entire organization; all are involved in its application; the participation is determined by conviction; methodology is particularly directed toward prevention; it aims to do the right things “from the beginning”; the responsibility and the involvement of everyone from organization.

But the use of excellence models and quality norms are only recommended and used on voluntary basis in many public administration systems, especially in Central and Eastern European countries. As far as the measuring of language certification quality is concerned, the current systems should be analyzed trough the self-evaluation of test center based on the EFQM model, and the evaluation of stakeholders and examinee satisfaction should based on various surveys organized at a national level, in order to know their needs better. But scholar pointed out that the introduction of self-assessment methodology and the organizational quality management systems have progressed to a certain extent, but the self-evaluation just begun to develop (Matei, 2011, p. 94). Therefore, the introduction of elements of quality management system in the case of state language proficiency examination for civil servants is determined by internal factors and, in general, closely related to administrative practices.

In search of solutions to language certification challenges: discrepancies between idea and implementation

The role and impact of the administration are not always taken into account when analysing language policy. Most researchers explore the peculiarities of national identity, some shed a light on a mixture of language and ethnicity questions.

The situation with the use of the state language in the public sector in Baltic states on the eve of the collapse of the USSR was quite similar to that which developed in other soviet republics (see table 1).

Table 1: Population of Baltic states according to the 1989 All-Union Census of Population (3 main ethnic groups dimension), Demoscope, own calculations

Country	Etnnic group	Numbers	%
Lithuania	Lithuanians	2,924,251	79,6
	Russians	344,455	9,4
	Poles	257,994	7
Latvia	Latvians	1,387,757	52
	Russians	905,515	34
	Belarussians	119,702	4,5
Estonia	Estonians	963,281	61,5

	Russians	474,834	30,3
	Ukrainians	48,271	3,1

At the same time, the Russian language was considered to be the mother tongue for most Ukrainians and Belorussians (Kotyhorenko 2005, 51) in view of the consistent policy of Russification in the former soviet socialistic republics, in the framework of the Soviet course for "the rapprochement, and in fact the merger of socialist nations" (Dzuba 2011, 460) the Russian language dominated in all spheres of social life.

Moreover, Russian aggression in 2014 raised up the value of Ukrainian as the national language and created internal motives not only for civil society, but for the state institutions. Although this movement didn't lead to a drastic change in language practice, all the more so because the state did not insist on the use of Ukrainian even in the public sector (Kulyk 2016).

However, we can see the opposite approach in the Baltic states. Estonia, Latvia and Lithuania built their governmental bodies and security services almost from scratch. They chose to set up their own civil services, national armies and security services. At least, this guarantees that their civil servants, military forces and security agencies will not turn into the branches of similar Russian services, stuffed with the agents of the Kremlin's influence. Obviously, the process was not easy as some recruited servants of the new governmental bodies lacked professionalism. Moreover, the linguistic situation differed in the attitudes of titular elites and masses toward their national language which was much more positive in the Baltic states, thus enabling more resolute and supportive policies. Similarity of the linguistic situations in the Baltic states at the end of the Soviet rule is much based not on the share of people declaring the titular language as native in censuses, but on the gap between linguistic and ethnonational identification resulting from the Soviet combination of ethnic primordialism and linguistic Russification (Onuch and Hale 2018, 101; Kulyk 2014).

Formation and implementation of language quality management system in civil service

The issue of using the state language in the civil service became especially acute in the Baltic states after restitution of their independence in 1991. That was predetermined both by total russification of the public sector during the Soviet occupation and by the ethnic composition of the population (Hogan-Brun et. al. 2008: 67). Accordingly, the use of the state language in the public sector and in the civil service in particular turned into one of the main requirements in the Baltic states after gaining their independence because they "saw themselves as unitary states that were indeed multilingual (as they had always been) but as states in which the national language would be the language in which all essential social functions were to be conducted" (p. 81). Consequently, "knowledge of the state language became an important factor for the integration of ethnic minorities into a changing society" (p. 132). As a result, it was quite natural that the experience of implementation of the state language and the modern language policy in the field of the civil service in these states are extremely similar.

A QMS is based on processes (what should be done), procedures (how the process should be done) and working instructions (how procedures should be performed). When applied to the state language proficiency examination, the QMS will have to meet all ISO 9001 requirements, including documentation conditions. Some of the key components of a QMS include:

- a system that is repeatable, quantifiable and constantly improving
- documented information (such as procedures, working instructions, forms) in order to achieve the pre-defined quality
- external or internal revision to ensure compliance with requirements

One of the best-known standards which was implemented by many public bodies is ISO 9001:2015, Quality management systems – Requirements, which defines the set of requirements for a QMS to help institutions to be more efficient and improve their relations with business, civil societies and citizens.

The development of the Common European Framework of Reference for Languages: Learning, Teaching, Assessment (CEFR) is based on several objectives which are similar to quality management goals (Bärenfänger, O. 2008).

Both, and even more bodies of language learning standards, are certainly needed because standards must to a certain extent be customized for and calibrated to the local (i.e., national- or regional-level) language learning environment. From a practical perspective, standards may be used to regulate learning, and people and educators most certainly may want any language learning regulation to be at a more national or regional level (Cox, 2018).

First of all, the language issue was raised in the Baltic states laws on citizenship. Only Lithuania, where the majority of the population were ethnic Lithuanians, adopted a so-called zero option immediately after the collapse of the USSR in 1991 proclaiming all legitimate residents, excluding military, Committee for State Security (KGB) and other temporary units as citizens. However, in two next years the Government of the Republic of Lithuania passed a Resolution No. 314 "Concerning the qualification categories of the knowledge of the national language" (1992) and a Resolution No. 145 "Concerning article 12 on the citizenship of the Republic of Lithuania and the Lithuanian language and Lithuanian Constitution fundamentals examinations" (1993), introducing an examination in the Lithuanian language and the fundamentals of the Lithuanian Constitution as an mandatory condition for getting citizenship and language categorical examination for those who wanted to hold a particular job. Estonia and Latvia also proclaimed basic competence in Estonian and Latvian as one of the main requirements for the naturalization (Alien law of 1993, revised into the current version in 1995, in Estonia and Alien law of 1994 in Latvia). Accordingly, applicants for citizenship had to demonstrate "basic writing, reading and speaking level of competence" (p. 83).

Simultaneously the language legislation which had existed in times of USSR occupation was substantially revised, and new principles for language policy, which are relevant nowadays, were developed in the Baltic states. The main objective of the national language policy in the states, which was enunciated in each constitution and detailed in the language laws, is "to guarantee the status of Estonian, Latvian and Lithuanian as the only official language in each republic. Estonia's was passed in 1995, Latvia's in 1999 and Lithuania's in 1995" (p. 103).

Introduction of a "systematic language certification for employment purposes" became an important provision of these laws and the accompanying legislative acts. The examinations procedures had "a common core: all those people who had not undergone an education in the respective national language (Estonian, Latvian or Lithuanian), and who were employed in defined occupations, needed to demonstrate a level of knowledge of the national language appropriate to their level of employment. In Lithuania, this requirement targeted only those in the public sector; in Estonia and Latvia this requirement extended to all personnel in employment, public or private, who had contact with the public" (p. 85). In order to ensure state control over this certification state language offices were established in all the states. Researches admit that "the need to gain language certification was the most significant reason for those who had no proficiency in the national language to learn that language" (p. 85).

With the aim of evaluating a linguistic competence of civil servants all the states initially developed their own scales, which eventually proved to be quite similar. In Estonia before 2008 there was a three-level system of evaluation: beginner, intermediate and advanced. In Latvia from 1992 to 2000 a system of three levels of state language proficiency existed: the first (the lowest), the second and the third (the highest), which were divided into sublevels 1A and 1B, 2A and 2B, 3A and 3B from 2000 to 2009. In Lithuania three categories from the first (the lowest) to the third (the highest) were established in 1992, and they are still actual there. Various positions in the public sector required specific levels of knowledge of the state language. However, in November 2001 a European Union Council resolution recommended using the CEFR to set up systems of validation of language ability, and the Baltic states governments takes it as a base for their own systems of language proficiency assessment.

Nowadays the requirements for the Baltic states language proficiency as well as its assessment and testing are established by Estonian Language act of 23 February 2011, Latvian State language law of 21 December 1999 and the Republic of Lithuania Law on the state language No. I-779 of 31 January 1995, which proclaim an official status of the national language of each republic.

Therefore, in section 10 (1) of Estonian Language act it is determined that "the language of public administration in state agencies and local government authorities is Estonian", and, according to section 23 (1), "officials and employees of state agencies and of local government authorities, as well as employees of legal people in public law and agencies thereof, members of legal people in public law, notaries, bailiffs ‹…› shall be able to understand and use Estonian at the level which is necessary to perform their service or employment duties" (Language act 2011). Almost the same provision can be met in section 6 of the Latvian State language law: "Employees of state and local government institutions, courts and institutions constituting the judicial system, state and local government undertakings" should be "fluent in and use the official language to the extent necessary for performance of their professional duties and duties of office" (State language law 1999). Article 6 of the Republic of Lithuania Law on the state language proclaims that among other institutions "heads, employees and officers of state and local government institutions providing services to the population ‹…› must know the state language according to the language knowledge categories, established by the Government of the Republic of Lithuania" (Law on the state language No. I-779, 1995).

The same requirements can be found in section 14 of the Estonian Public service act of 25 January 1995, in section 7 of the Latvian Law on the state civil service of 22 September 2000 and in article 9 of the Republic of Lithuania Law on public service No. VIII-1316 of 8 July 1999.

Furthermore, sections 24–27 of Estonian Language act also set out some basic requirements for the Estonian language proficiency examination and proclaim that the primary responsibility for its organization (providing preparation for the exam, developing tasks and forming their bank, issuing certificates of language proficiency, approving of examination commissions) is entrusted to Ministry of Education and Research and directly to its head, whereas in Latvian and Lithuanian legislation these aspects are established in a number of governmental regulations and resolutions.

The detailed requirements to the language proficiency level of civil servants, description of the structure and the procedure of the state language proficiency examination are established by regulation of the Ministry of Education and Research in Estonia, regulations of the Cabinet of Ministers in Latvia and resolutions of the Government in the Republic of Lithuania (see Table 2).

Those, who, in accordance with the procedure established by the Republic of Lithuania law on the legal status of occupations (Official Gazette No. 66-1609, 1997), were victims of occupations from 1939–1990, as victims of occupations, do not apply the state language category for one year after their return to the Republic of Lithuania
Coast of examination session	Free	State fee	State fee

All the Baltic states language legislation proclaims the only state form of the language proficiency examination and provides state funding for institutions that deal with the development of tasks and recommendations for the preparation, as well as with organization, carrying out and assessment of testing. Furthermore, passing the examination is free in Estonia, while there is a minor state fee with a number of privileges in Latvia and Lithuania. Also in Estonia individuals who have passed the Estonian language proficiency examination and have been issued the certificate are reimbursed for the costs of language learning to the extent established by the Government of the Republic (see http://www.innove.ee/en/language-examination).

In all the states the subjects directly involved in taking the exam and verifying its results are state language proficiency commissions which work on the basis either of special educational and testing centers (Estonia, Latvia) or secondary and higher educational institutions (Lithuania). The commissions include employees of these institutions who are required to have a higher philological or pedagogical education, and their candidacies are approved by the Minister of Education and Research in Estonia, the head of the National Centre for Education in Latvia and the head of the National Centre of Examination in Lithuania.

Control over the activities of these commissions is carried out by the National Examination and Qualification Centre of the Foundation Innove in Estonia, the State Language Proficiency Testing Department of the National Centre for Education and the Ministry of Education and Science in Latvia and the State Language Department of the Teachers Professional Development Centre and the National Centre of Examination in Lithuania. The whole information on the official language examinations organized by the institutions and tests sample are available on their web-sites. The duties and powers of all the organizations are similar, and they all work under the guidance of the Ministry of Education and Science of each country. Representatives of these organizations can attend the exam without prior warning, checking the competence of both the examinees and the examiners. Moreover, the Lithuanian Teachers Professional Development Centre organizes qualification improvement events for the members of the state language proficiency commissions.

It is also noteworthy that all the controlling bodies are members of the Association of Language Testers in Europe (ALTE), and they conduct the development of examinations tasks and requirements for linguistic competence according to its recommendations. But only Estonian testing institution became ALTE Members. Foundation Innove undergo a strict ALTE audit of A2-C1 qualifications and success in an audit results in a Q-Mark being awarded for those qualifications. Thus, in Estonia language proficiency examination is available on four levels, which correspond to the CEFR (A2, B1, B2, C1) (section 5 of the Amendment act to the Language act of 8 February 2007). In Latvia according to the Cabinet of Ministers regulation No. 733 of 7 July 2009 the scope of the official language knowledge is divided into three proficiency levels: A, B and C, and each of them has two degrees—the lowest first and the highest second. In Lithuania three state language knowledge qualification categories have been confirmed in the Government of the Republic of Lithuania resolution No. 1687 of 24 December 2003. According to it these categories correspond to A2, B1 and B2 levels of the CEFR. The C-level in Lithuanian state language proficiency examination does not exist.

A certain level of the Baltic languages is required to get a job in different civil services. In Estonia these requirements for various civil servants are described in the Regulation of the Government of the Republic No. 105 of 26 June 2008. According to it, language proficiency at B1 and B2 levels is required of civil servants, whose duties may be related to administration and management of subunits or the compiling of documents, and C1-level is required of civil servants, whose duties are management of departments, planning and coordination of their activities or providing consultation and the preparation of public speeches and text of official correspondence. As for C2, in Estonia positions requiring the linguistic competence at this level are not legally defined.

In Latvia the requirements to the language proficiency of civil servants are higher than in Estonia. According to the Cabinet of Ministers regulation No. 733 of 7 July 2009, C1 is compulsory for members of the municipal governments, deputies of the municipal government of the region, the governors / presidents of the councils, membership of the councils, budget unit managers, employment departments managers, etc., and C2 is necessary for the representatives of the highest public administration authorities and their units.

In Lithuania according to the Government of the Republic of Lithuania resolution No. 1688 of 24 December 2003 those state servants "whose posts are classified in grades B and C need to have the second category if they are required to communicate with the people on a regular basis and / or fill in papers" (Resolution No. 1688, 2003). And "the third category of the state language shall be applied to heads of state and municipal institutions, bodies, enterprises and organizations, civil servants whose posts are assigned to A-grade1" (Resolution No. 1688, 2003).

[1] According to The Government of the Republic of Lithuania resolution No. 693A "The approval of the description and assessment methodology of state civil service representatives and on the functions of the state

The list of categories of citizens who do not need to pass the language proficiency examinations is also almost identical in the Baltic states (see Table 1). The main general requirement is completed basic, secondary or higher education in accredited programs in the state and passing the centralized examination in it.

The main requirements to the structure of the language proficiency examination in the Baltic states are slightly different and quite similar to the patterns of Cambridge examinations, IELTS and TOEFL. The examination indicates abilities of examinees to understand the information they read or listen to, to write texts of different styles and genres, to be fluent in different communicative situations. The tasks aim to reflect everyday professional situations as close as possible. Their detailed description is given in the Estonian Ministry of Education and Research regulation No. 24 of 13 June 2011, Latvian Cabinet of Ministers regulation No. 733 of 7 July 2009, The Government of the Republic of Lithuania resolution No. 1688 of 24 December 2003 and The Minister of Education and Science of the Republic of Lithuania order No. ISAK-286 of 1 March 2004.

The examinations are divided into two parts – written and oral. In Estonia and Latvia written part consists of reading, listening and writing sections, and in Lithuania there are also use of the language tasks added, as well as in some Cambridge examinations. Accordingly, in Estonian and Latvian versions of the examination each part gives a maximum of 25 % of the final result, while in Lithuanian it is 20 %, and any part must not be 0 points. The test is passed if at least 60 % of total points is achieved in Estonia, 50 % in Latvia and 55 % (with at least 50 % of each part) in Lithuania. Furthermore, in Estonia candidates who fail to meet the minimum threshold of 35 % of maximum points cannot retake the test until 6 months after their last test.

In Latvia, if a person does not pass the examination, his or her higher level of proficiency in the state language may be reviewed no earlier than 3 months after the last check. And if it is determined that during the inspection a person has performed unlawful acts within the meaning of the Code of administrative offenses, the National Centre for Education shall not issue a state language proficiency certificate to the examinee and cancel the results of the testing. In this case, the person may repeat the test no earlier than 6 months after the inspection. If a candidate refuses to take some part of the examination (listening, reading, writing or speaking skills) or performs unlawful acts, his or her state language proficiency is not assessed.
In each state types of the tasks, their amount, complexity and duration of carrying out vary according to the different levels. Typical tasks for B1–C2 levels are:

1. *Writing* — 1) private or official letter, e-mail, summary, based on the source data (e.g. diagrams, photographs, maps, schemes, etc.); 2) essay, review, article, report.

2. *Listening* — monologues and dialogues with multiple choice, true/false, gap-filling, cloze, matching and open questions.

3. *Reading* — multiple choice (complete the sentence or choose the right answer to the question), matching (paragraphs to headings, texts to their annotations or topics), gap-filling, true/false, cloze and open questions.

4. *Use of Language* (only for Lithuania) — gap-filling with right personal / impersonal verb forms, words buildings and transformation tasks.

5. *Speaking* — 1) general introductory interview; 2) short presentation on a topic related to the field of work or conducting a conversation with the examiner according to the given plan; 3) discussion on some topic using topic and argument cards; describing pictures and answering related questions. Speaking section is a conversation between an examiner and one (Latvia, Lithuania) or two (Estonia) examinees. The examiner takes the examination, strictly basing on instructions. The conversation is recorded, and each examination is assessed independently by two evaluators.

The highest levels of the testing require knowledge of the specific vocabulary because reading tasks base on public information about institutions and enterprises, texts of manuals, information about services or products, reviews, fiction, newspapers and magazines articles or popular science articles, listening section needs understanding lectures, presentations, business conversations, and speaking tasks include topics related to the examinee's field of work.

---

service management" of 19 June 2000, there are three grades of civil servants: A, in which the necessary obligations of the position require a higher university or equivalent education, B, in which the necessary obligations of the position require a higher education or equivalent (specialized secondary education — technical schools) and C, in which the necessary obligations require at least secondary education and vocational qualification.

Results of the examinations shall be announced to the candidates not later than within 3 working days after the testing in Lithuania, within 15 working days in Latvia and within 30 working days in Estonia, and can be appealed if a person is not satisfied with them. The received certificate has no limitations on its validity period. Furthermore, language proficiency certificates issued before each state brought the national assessment system into conformity with CEFR are not replaced, nor it is required to re-take the examination.

A notable peculiarity of the Baltic states language legislation is that their state language proficiency examinations perform a dual function: they do not only testify the level of an employee's linguistic competence but also allow to confirm the level of language proficiency which is necessary to apply for citizenship. In Estonia a minimum level of B1 is required for the naturalization procedure, in Latvia and Lithuania it is A2 (first category).

In all the Baltic states "the period of most extensive testing occurred from the early to the mid-1990s when over 200,000 tests were taken and passed in Estonia, more than twice as many in Latvia and about 25,000 in Lithuania" (Hogan-Brun *et. al.* 2008: 128). In the 2000s this number~~s~~ has decreased significantly. For instance, in 2016 only 5,200 people in Estonia and only 4,790 people in Latvia took the state language proficiency examination (see statistics of the Innove Foundation at http://www.innove.ee/et/eesti-keele-tasemeeksamid/tasemeeksamite-statistika-ja-analyysid and of the Latvian National Centre for Education at http://visc.gov.lv/valval/dokumenti/2016_statistika.pdf). In our opinion, these data confirm the effectiveness of language policy and coverage of a great number of people wishing to apply for citizenship and employees by language proficiency testing in the Baltic states.

Conclusions and suggestions for further research

The Baltic countries restoration of independence and the historic separation from the Soviet Union have found logical imprint on the language legislation which was substantially revised during the first years of rebirth, and new principles for language policy such as "systematic language certification for employment purposes" were incorporated. The Baltic states societies considered the "Russification" program as an instrument of introducing official "language of occupation", which would hinder the possible process of reconciliation.

Period of soviet occupation gave a "Carte Blanche" for Baltic state governments for used more hard ("sticks") than soft ("carrots") language policies by setting requirements, practicing control and letting the solutions come from the civil society organisations. Ruling elites and citizens were mostly agreed on the language policy balance between minority rights and the ensuring of social stability. Attitudes of titular elites and civic activists toward their national language were positive, thus enabling more complex language certification policies in civil service.

Regarding theoretical background the QMS of the state language proficiency examination is intended to an be integrative element which brings together aspects of the public institution, the civil society and customer language identification, integrating civil servants (skills, roles and responsibilities), processes (workflow, interactions), state regulatory requirements, technology, risks and opportunities, with the main purpose of delivering the best language proficiency.

It is necessary that the process of planning certification and control are carried out in a centralized fashion by a single state institution. As a minimum, such a center must take care of the tasks preparation and the development of clear criteria for their evaluation, send tasks through secure communications to the licensed higher educational institutions that carry out only representative and organizational functions, and verify the work performed. In some cases trying to implement a strict language policy, it was useful to open additional positions of special language inspectors with authority to demand administrative fines.

Regarding the improvement and unification of the certification evaluation methodology: the authors of the international IELTS, TOEFL and Cambridge examinations (BEC, FCE, CAE, etc.) offer a qualitative solution to this issue, in which the evaluation method clearly specifies the language competencies for each level of English language proficiency. In general, the basis for ranking the language and communicative competence of civil servants has been taken from the CEFR. Nowdays only Estonian testing institution has received the ALTE Q-mark which show that their exams have meet all the core requirements of ALTE's 17 quality standards. But those standards are not fully cover the evaluation of stakeholders and examinee satisfaction. It was found that communication procedures haven't enough feedback instruments and mostly build on providing information to stakeholders and examinee.

Also, convergence of the certification evaluation methodology implies the existence of common structures or similar structures to implement language certification in Baltic states public institutions and implicitly in implementing the elements of quality management, but self-evaluation practices are only starting to be implemented.

Suggestions for future research include a study of implementation the quality management tools in all central and local institutions of public administration, an examination of communication between native- and second-language speakers. One might also consider a sociolinguistic mapping of an public institutions, identifying relevant speech communities and assessing to what extent social interaction and knowledge-sharing are affected by the use of a second language.

Resumen

En la mayoría de los estudios sobre distribución de ingresos personales se analizan las distribuciones no condicionales de toda la población. Tal tipo de análisis es relevante para las políticas públicas. Sin embargo, existe una brecha importante de falta de conocimiento acerca de las distribuciones de los ingresos personales condicionales a las características socio-demográficas y de comportamiento de ingresos por tipo de individuos. Este conocimiento además es de gran relevancia práctica para el diseño mejor focalizado de políticas públicas. Este trabajo presenta una contribución exploratoria en la dirección de utilizar técnicas estadísticas no supervisadas de análisis de agrupamiento con datos longitudinales para identificar tales distribuciones condicionales de los ingresos personales por tipos de individuos. Para realizar este análisis, usamos la Encuesta Nacional de Hogares (ENAHO) del Perú entre los años 2015-2018. Encontramos que, en lugar de una sola distribución no condicional de ingresos personales, se logran identificar cuatro distribuciones de ingresos condicionales distintas de acuerdo a las características socio-demográficas de los individuos y del comportamiento inter-temporal de sus ingresos. La aplicación se realiza evaluando varios modelos de agrupamiento bajo diversos criterios de validez interna, estabilidad, y número de grupos óptimo.

Palabras clave: Análisis de Clúster, Distribución de Ingreso Condicional, Ingreso personal.

Introducción

La forma en que se distribuyen los ingresos entre los hogares e individuos que componen una población ha sido un tema de interés recurrente en economía y otras ciencias sociales (Cowell, 2007). El análisis distributivo permite evaluar que tan igualitaria o desigual es la repartición de los recursos que se generan a lo interno de un país, región o comunidad. Lo cual no solamente es de interés para la economía, sino también para otras disciplinas de las ciencias sociales, puesto que la distribución de ingresos tiene efectos sociales, demográficos y políticos muy importantes (Roine & Waldenström, 2015; Rözer & Kraaykamp, 2013). La distribución de ingresos puede ser estudiada desde dos perspectivas, funcional y personal, las cuales se encuentran estrechamente relacionadas (Perotti, 1993). La distribución funcional del ingreso se define como la asignación de los recursos en los factores de producción. Mientras que, la distribución personal del ingreso considera como unidad de análisis a los hogares o individuos (Atkinson, 1997).

En la actualidad existe evidencia empírica que respalda el hallazgo estilizado de que las *distribuciones de ingresos* de los individuos dentro de una población tienen una forma asimétrica positiva y que en general pueden ser representadas mediante algunas distribuciones teóricas conocidas, tales como la *Pareto* (Champernowne, 1953) y la *Log-normal* (Souma, 2001; Dagum, 2014). Algunos autores, han investigado también el ajuste de la distribución de ingresos a otros modelos de probabilidad (Colombi, 1990; McDonald, 2008; Richmond, Hutzler, Coelho, & Repetowicz, 2006). Si bien, la distribución del ingreso personal es afectada por variables macroeconómicas, tales como el producto interno bruto, la tasa de ocupación (García, Prieto-Alaiz, & Simón, 2013), y la inversión en capital humano (Galor & Zeira, 1993), dicha distribución también varía de acuerdo a las características de los individuos. Por ejemplo, según su oficio o profesión (Mohun, 2016), nivel de escolaridad (Becker, 1964), grupo etario, sexo, y etnia (Atkinson & Bourguignon, 2000).

La distribución de ingresos de los individuos según sus características es llamada *distribución condicional del ingreso* y ha sido estudiada previamente usando diversas variables condicionales (Biewen & Jenkins, 2005; Pudney, 1999;

Quintano & D'Agostino, 2006). Conocer que los individuos tienen distintas distribuciones de ingresos de acuerdo a sus características nos permite evaluar que individuos con un conjunto de características similares puedan tener distribuciones que no se adhieran a las características generales de toda la población.

En la práctica, el tomar decisiones de política pública no estaría suficientemente justificado cuando se adopta el supuesto de que todas las distribuciones de ingresos de los individuos condicionales a sus características socio-demográficas, siguen el mismo modelo de probabilidad. Ello, porque tanto las fuentes de ingresos, como las circunstancias bajo las cuáles las personas generan dichos ingresos son heterogéneas. Por otra parte, tanto las características, como las necesidades que suplen las personas de una población según los ingresos que perciben, son distintas (Deaton, 1997). Asimismo, se debe tener en cuenta que los individuos experimentan cambios en su proceso generador de ingresos a través del tiempo, ya sea por la típica dinámica del ciclo de vida (Ando & Modigliani, 1963), o porque los procesos de acumulación de capital humano, emprendimiento, innovación, o el cambio en sus preferencias, generan, a su vez, cambios estructurales en las funciones de producción de tales ingresos a lo largo de la vida (Eckstein et al., 2016).

En el estado actual del conocimiento en economía, aún se ha avanzado poco en el desarrollo de algoritmos que permitan identificar las distribuciones de ingreso por tipos de individuos según sus características. En nuestro mejor conocimiento, los pocos esfuerzos en esta dirección se han focalizado en generar tipologías de hogar para construir *Matrices de Contabilidad Social* en el marco de los *Modelos de Equilibrio General Computable* (véase, por ejemplo: Thorbecke & Jung, 1996; Decaluwe et al., 1999). Sin embargo, existe una brecha importante no explorada en la aplicación de técnicas de aprendizaje estadístico no supervisado para este propósito. En este trabajo realizamos una contribución en esta dirección, al explorar en la aplicación de una técnica de aprendizaje estadístico no supervisado, como es, el análisis de clúster, para generar grupos de individuos adultos con similares características socio-demográficas y distribucionales. En la aplicación se usan variables de agrupamiento que provienen de tanto de una estimación econométrica de la conocida ecuación de Mincer (1974), así como, de algunos parámetros de la distribución temporal de ingresos individual, tales como la dispersión medida por el rango y la asimetría medida conforme el índice propuesto por Groeneveld & Meeden (1984).

Partimos del supuesto de que en una población existen tipologías de individuos que comparten entre sí su propio modelo de distribución de ingresos condicional dentro de una ventana de tiempo acotada, en que su proceso generador de ingresos no experimenta cambios estructurales. Es decir, suponemos, razonablemente, que el proceso generador de ingresos es fuertemente estacionario solamente entre ciertos tipos de individuos que comparten un conjunto de características socio-demográficas y en el marco de ventanas de tiempo acotadas. Suponemos, además, que estas distribuciones estacionarias por tipos de individuos y ventanas temporales pueden ser observables a través de datos de paneles cortos con alrededor de cuatro olas anuales, ya que solamente en un lapso de tiempo razonablemente acotado se puede esperar que las personas no experimenten cambios estructurales importantes en su proceso generador de ingresos.

La pertinencia del estudio en términos de su utilidad práctica es que la identificación de tales grupos permitiría aplicar políticas públicas mejor informadas y con una focalización más efectiva, al contar con información más detallada de cómo son las distribuciones de ingresos condicionales por tipos de individuos (Ravallion & Chao, 1989). Ello permitiría un mayor impacto social en lograr objetivos de política que contribuyan a mejorar el nivel y la estabilidad de los ingresos de los individuos y de los hogares, especialmente entre los más vulnerables.

El artículo está organizado como se indica a continuación. La sección Metodología presenta los datos y técnicas a utilizar, en la sección Resultados y Discusión se muestran tablas y gráficos relativos al proceso y al producto final del estudio junto a un análisis del mismo. Cerrando con la sección Conclusiones que incluye las observaciones finales y presenta los trabajos futuros.

Metodología

Esta sección se describen los datos y las variables generadas para realizar el agrupamiento. Seguidamente se detallan las técnicas de agrupamiento utilizadas, así como los criterios para definir el número de grupos. Finalmente, se enuncian las hipótesis a evaluar.

Datos Utilizados

Los datos utilizados provienen de la Encuesta Nacional de Hogares (ENAHO) de Perú, en su modalidad de panel, para el período 2015-2018. Se trata de una encuesta longitudinal con cuatro olas anuales. Esta encuesta contiene información detallada de personas y hogares de zonas urbanas y rurales, incluyendo datos vivienda, características de los miembros del hogar, datos de salud, así como ingresos y gastos de los hogares y de los individuos.

El tipo de datos seleccionado para el estudio es apropiado por tres razones. Primero, porque que contiene la información necesaria para el estudio en términos de variables socio-demográficas de los individuos. Segundo, porque al ser un panel, permite aprovechar la dimensión temporal para obtener algunos parámetros básicos de las distribuciones individuales de ingresos, tales como la dispersión de ingresos del período y su asimetría. Tercero, porque comprende justamente una ventana de tiempo de cuatro años, período que se considera óptimo para acotar la temporalidad a una fase en que se minimicen los cambios estructurales del proceso generador de ingresos. La elección de ventanas temporales de cuatro años, es apropiada porque tal longitud representa un período que cumpliría tres requisitos relevantes: (i) *información mínima*, en el sentido que en ventanas más cortas, el número de observaciones temporales (menos de cuatro) sería críticamente poco informativo; (ii) *estacionariedad fuerte en el proceso estocástico,* en el sentido de que es una ventana en que es razonable asumir que las distribuciones permanecen constantes, porque haría falta un lapso de más de cuatro años, para que los individuos adultos experimenten cambios estructurales relevantes; y (iii) *evasión del desgaste de panel*, ya que se trata de una ventana temporal en que empíricamente el desgaste de panel aún no se ha vuelto crítico.

El panel ENAHO del Perú para los años 2015-2018 contiene 3,783 hogares comparables, de los cuales 1,299 individuos informan su ingreso autónomo en todos los periodos. La variable de referencia para determinar las distribuciones de ingresos es el logaritmo natural del ingreso autónomo de las personas ajustado por inflación. Esta variable no se toma como instrumento para agrupar, sino solamente como referencia para validar el agrupamiento, una vez obtenidos los resultados.

Para implementar el análisis de clúster se utilizaron cuatro variables de agrupamiento que reflejarían parámetros claves de las distribuciones de ingresos individuales. Dos de estas variables provienen de la estimación econométrica de la media condicional a través de una ecuación de Mincer (1974). Esta ecuación se estima por el procedimiento de Amemiya & MaCurdy (1986), el cual permite explotar las ventajas que ofrecen los datos longitudinales al brindar estimadores insesgados y consistentes de los parámetros del modelo de regresión. Este tipo de modelo permite además utilizar como regresores tanto variables métricas que cambian sus valores a través del tiempo, como variables categóricas que son invariantes a través del tiempo (ej., el género, la condición étnica y la ubicación de residencia rural/urbana). La ecuación estimada es la siguiente:

$$\ln w_{it} = \mathrm{x}_{it}'\beta + \mathrm{z}_i'\gamma + \phi_i + \varepsilon_{it} \tag{1}$$

donde $\ln w_{it}$ es el logaritmo natural del ingreso de la persona i en el período t; x_{it} y z_i son vectores de variables que son variantes e invariantes en el tiempo respectivamente, algunas de las cuales son endógenas y otras exógenas; ϕ_i es un efecto individual de la persona i; ε_{it} es un efecto aleatorio, mientras que β y γ son vectores. de parámetros a estimar. Como variables explicativas del modelo se incluyeron los años de escolaridad de la persona, los años de escolaridad al cuadrado, los años de experiencia (aproximados como la edad, menos los años de escolaridad, menos 6), los años de experiencia al cuadrado, así como variables dicotómicas para el género, la pertenencia a una etnia indígena, la localización de residencia en zona rural y el laborar como trabajador independiente. Dentro de este conjunto de variables explicativas, las que se consideraron endógenas fueron las siguientes: los años de escolaridad de la persona, los años de escolaridad al cuadrado, los años de experiencia y los años de experiencia al cuadrado. Como es conocido en la literatura desde los trabajos de Becker (1964) y la ecuación de salarios de Mincer (1974), los ingresos laborales de las personas están fuertemente determinados por la escolaridad y la experiencia, así como por el resto de variables incluidas en el modelo, las cuales afectan los ingresos a través de mecanismos de discriminación (género y etnia indígena) y de las estructuras productivas locales (ruralidad. y trabajo independiente) (De Janvry & Sadoulet, 2000, Mason, 2012).

A partir de los resultados de dicha estimación econométrica se obtuvieron las siguientes variables de agrupamiento: (i) el promedio del logaritmo del ingreso determinado por las variables explicativas x_{it} y z_i, el cual se determinó conforme el siguiente componente de la ecuación de Mincer: $\mathrm{x}_{it}'\hat{\beta} + \mathrm{z}_i'\hat{\gamma}$, donde $\hat{\beta}$ y $\hat{\gamma}$ son los estimadores de los parámetros correspondientes; y (ii) el efecto individual ϕ_i. La intuición que está detrás de la definición de estas variables de agrupamiento es que la media de la variable de referencia se descompone en un elemento determinístico dado por las características observables contenidas en los vectores x_{it} y z_i, así como por un efecto idiosincrático inobservable capturado por el componente de efecto individual ϕ_i. Este componente individual se debe entre otros a factores como la habilidad intelectual, las redes y contactos sociales que posee la persona, sus habilidades blandas,

sus antecedentes familiares, etcétera; todos los cuales son inobservables en los datos. Las otras dos variables de agrupamiento utilizadas corresponden a una medida de dispersión y una medida de asimetría. Como medida de dispersión se utilizó el rango en lugar de la varianza, debido a que el número de datos es muy reducido para calcular la varianza (cuatro observaciones temporales). Con respecto a la asimetría, se tomó la medida propuesta por Groeneveld & Meeden (1984), la cual está basada en las distancias de los extremos del rango y la mediana. Esta medida se define tal como se indica a continuación:

$$A_{GM} = \frac{r\left(y \middle| y \geq y_m\right) - r\left(y \middle| y \leq y_m\right)}{r\left(y \middle| y \geq y_m\right) + r\left(y \middle| y \leq y_m\right)} \tag{2}$$

donde $r\left(y \middle| c\right)$ es el rango de la variable de interés y (en nuestro caso el logaritmo natural del ingreso autónomo de la persona) dada la condición c, y donde y_m es el valor de la mediana para dicha variable.

La Tabla 1 presenta tanto las estadísticas descriptivas de la variable de referencia como de las variables de agrupamiento con sus correspondientes correlaciones. Se puede observar que las correlaciones entre las variables de agrupamiento no son tan altas como para afectar los resultados del análisis de clúster.

Tabla 1: Estadísticas descriptivas del logaritmo del ingreso y de las variables de agrupamiento.

Variable	***Media***	***Desvío Estándar***	**1**	**2**	**3**	**4**
1. Promedio del logaritmo del ingreso autónomo del individuo	9.54	0.76				
2. Promedio del estimado del logaritmo del ingreso autónomo del individuo a partir de determinantes observables del ingreso	9.52	0.65	.51**			
			[.47, .55]			
3. Rango del logaritmo del ingreso autónomo del individuo	0.76	0.69	-.44**	-.26**		
			[-.48, -.40]	[-.31, -.21]		
4. Medida de asimetría del ingreso autónomo del individuo	-0.05	0.47	.09**	.11**	-.20**	
			[.04, .14]	[.06, .16]	[-.25, -.14]	
5. Efecto individual del ingreso autónomo del individuo	0.02	0.66	.61**	-.37**	-.23**	-.00
			[.57, .64]	[-.42, -.32]	[-.29, -.18]	[-.06, .05]

*Nota. Los valores entre corchetes indican intervalos de confianza al 95% para cada correlación. Mientras que los asteriscos indican la significancia estadística para los siguientes valores p: * indica p < .05, ** indica p < .01.*

Técnicas de agrupamiento utilizadas

Las técnicas de agrupamiento, conocidas también como técnicas de análisis de *clúster* por su origen lingüístico del inglés, comprenden una serie de métodos de aprendizaje estadístico *no supervisados* que permiten agrupar

observaciones en conjuntos homogéneos distintos entre sí (Milligan & Cooper, 1987). Existen diferentes métodos de agrupamiento, entre los cuáles, los más usados en la investigación aplicada son los procedimientos jerárquicos aglomerativos y los modelos no jerárquicos de las *k*-medias y las *k*-medianas (Jain, 2010). En el primer tipo de modelos se debe tomar la decisión de en qué etapa detener el algoritmo de generación de agrupamientos, es decir, en que momento cortar el árbol de agrupamiento conocido como *dendograma*. En los modelos no jerárquicos, en cambio, el investigador debe definir el número de grupos *k*, antes de aplicar el algoritmo correspondiente (*k*-medias o *k*-medianas). En ambos tipos de agrupamientos no jerárquicos existen algoritmos disponibles para determinar el número óptimo de grupos (véase: Charrad et al., 2014).

Para determinar el método de agrupamiento a utilizar, evaluamos la pertinencia de los tres algoritmos de agrupamiento indicados arriba, tanto a través de criterios de validación interna como de criterios de estabilidad y de número de grupos óptimo. Como criterios de validación interna se utilizaron: conectividad (Brock et al, 2008), silueta promedio (Rousseeuw, 1987), e índice de Dunn (1974). Mientras que, como criterios de estabilidad se usaron: la proporción media de no superposición (APN), la distancia promedio (AD), la distancia promedio entre medias (ADM), y la figura del mérito (FOM) (Datta & Datta, 2003; Yeung et al., 2001).

El criterio de la silueta (Rousseeuw, 1987) se basa en maximizar el promedio de la siguiente medida de silueta individual:

$$S(i) = \frac{b_i - a_i}{\max\{a_i, b_i\}} \tag{3}$$

donde a_i es la distancia promedio entre la observación i y todas las demás observaciones pertenecientes a su mismo grupo, mientras que b_i es la distancia promedio entre la observación i y las observaciones del grupo vecino más cercano. La silueta promedio se encuentra en el rango entre -1 y 1. Siendo mayor el agrupamiento cuyo número de clúster es el de mayor silueta promedio.

Para confirmar finalmente el número de grupos se realizó un análisis con múltiples estadísticas para este propósito (27 en total), utilizando el paquete NbClust disponible en el lenguaje de programación R (Charrad et al., 2014).

Hipótesis

El problema de investigación planteado es el de encontrar posibles distribuciones condicionales de ingresos bien diferenciadas entre sí para tipos de individuos adultos en una población. De acuerdo con este problema de investigación, se plantearon las siguientes hipótesis:

H_1.- Es posible identificar distribuciones condicionales de ingresos bien diferenciadas según las características socio-demográficas de los individuos y los parámetros básicos de sus ingresos en un panel corto de datos usando técnicas de agrupamiento.

H_2.- Las distribuciones condicionales de ingresos por tipos de individuos según sus características no se ajustan a las distribuciones no condicionales de ingresos asociadas a la población.

Para comprobar las hipótesis planteadas se aplicaron pruebas de Kolmogorov-Smirnov-Lilliefors (Lilliefors, 1969) de comparación entre pares distribuciones, bajo la hipótesis nula de que las distribuciones son iguales.

Resultados y discusión

La Tabla 2 presenta el resumen de resultados para la evaluación de la técnica de clúster más apropiada y del número de grupos óptimo según los criterios de validez interna y estabilidad. Vemos que dos de los tres criterios de validez interna: la conectividad y la silueta promedio, coinciden en que el número de grupos óptimo es cuatro. Sin embargo, ambos criterios difieren en el método de agrupamiento óptimo. De acuerdo con la conectividad el método jerárquico genera mayor cohesión interna dentro de los grupos y mayor separación con respecto a los grupos vecinos. Mientras que el criterio de la silueta promedio se inclina por el método de las *k*-medias. En cuanto a los criterios de estabilidad, vemos que en dos de ellos (APN y ADM) el método óptimo es *k*-medias, con cuatro grupos también.

Tabla 2. Número óptimo de grupos de acuerdo a criterios de validación interna y de estabilidad.

		Score	Método	Número grupos
Validación interna	Connectivity	275.112	hierarchical	4
	Dunn	0.027	hierarchical	9
	Silhouette	0.245	kmeans	4
Validación de estabilidad	APN	0.349	kmeans	4
	AD	1.739	kmeans	12
	ADM	0.770	kmeans	4
	FOM	0.896	kmeans	10

Al aplicar el análisis de número de grupos óptimo con el paquete de R NbClust para *k*-medias y distancia euclídea con las variables estandarizadas (ver Figura 1), el número de grupos con más adherencia entre los 27 criterios es también de cuatro grupos (8 de los 27 criterios seleccionan tal opción). Por lo cual, se decidió finalmente aplicar el análisis de clúster con *k*-medias y cuatro grupos.

Figura 1: Selección óptima del número de grupos con el método de K-medias basado en múltiples estadísticas.

En la Figura 2 se presenta el resultado del gráfico de agrupamiento en dos dimensiones, generado con el paquete Rtsne de R (Krijthe, J., et al., 2018). En el resultado se observa claramente una separación adecuada entre los grupos.

Figura 2: Representación gráfica en dos dimensiones de los datos agrupados usando t-SNE.

Los resultados de las pruebas MANOVA que se presentan en la Tabla 3, apuntan también a una adecuada separación de los grupos en términos de sus centroides. De acuerdo con los valores *p* correspondientes a los resultados de dichos contrastes estadísticos, en todos los casos se rechaza la hipótesis nula de igualdad de centroides entre los grupos conformados. De modo que existe evidencia para inclinarse en favor de la hipótesis alternativa, según la cual, hay diferencias estadísticamente significativas entre los centroides de los grupos.

Tabla 3: Análisis multivariado de varianza (MANOVA).

H0: Igualdad de centroides	Prov>F
Lambda de Wilks	0.000
Traza de Lawley-Hotelling	0.000
Traza de Pillai	0.000
Mayor raíz característica de Roy	0.000

Con la finalidad de observar las distribuciones obtenidas para los cuatro grupos conformados, la Figura 2 muestra las densidades del logaritmo del ingreso de cada grupo, generadas con la técnica Kernel (Silverman, 1986). Se puede observar que existen diferencias en las curvas generadas para cada grupo, tanto en su media, como en varianza, asimetría, y apuntalamiento. El grupo de menores ingresos (grupo 4 de color fucsia) es el de mayor varianza, lo cual estaría indicando que las personas. de menores recursos monetarios son también los que enfrentan un mayor riesgo. Este grupo muestra también la menor asimetría en su distribución de ingresos, lo cual, estaría denotando un mayor riesgo a la baja. Por su parte, el grupo de mayores ingresos (grupo 3 coloreado en celeste) es uno de los de menor varianza y mayor apuntalamiento. Este grupo por lo tanto sería uno de los que enfrenta un menor riesgo. Nótese, así mismo, que los dos grupos de mayor tamaño (grupos 1 y 2 coloreados en rosa y verde) corresponden a las personas de ingresos medios.

Figura 2: Distribuciones por grupo.

La Tabla 4 presenta las estadísticas resúmenes de cada distribución por grupo, mientras que en la Tabla 5 se muestran los centroides de los cuatro grupos conformados.

Tabla 4: Medidas resúmenes de las distribuciones condicionales encontradas.

Cluster	1	2	3	4
Media del logaritmo del ingreso	9.705	9.503	9.778	8.334
Varianza del logaritmo del ingreso	0.353	0.441	0.372	0.678
Asimetría del logaritmo del ingreso	0.016	0.256	-0.368	-0.866
Curtosis del logaritmo del ingreso	3.491	4.737	5.466	5.798

Tabla 5: Tamaños y centroides de los grupos conformados.

Cluster	1	2	3	4
Tamaño	415	395	370	119
Logaritmo del ingreso determinado por factores observables	9.854	8.846	9.958	9.221
Rango	0.52	0.763	0.501	2.352
Asimetría	-0.372	-0.083	0.435	-0.317
Efecto individual	-0.14	0.618	-0.17	-0.834

Finalmente, la Tabla 6 presenta los valores *p* correspondientes a los resultados de las pruebas de Kolmogorov-Smirnov-Lilliefors de comparaciones de distribuciones del logaritmo del ingreso de los individuos por pares de grupos, así como en su comparación con la distribución correspondiente para toda la población. De acuerdo con estos resultados, se encuentran diferencias estadísticamente significativas tanto entre las distribuciones de los grupos, como entre las distribuciones condicionales de cada grupo, comparadas con la distribución no condicional de la población. Se concluye entonces que todos los resultados están a favor de las hipótesis H_1 y H_2.

Tabla 6: Matriz de resultados de la prueba de Kolmogorov-Smirnov-Lilliefors (*p*-values).

Grupo	**1**	**2**	**3**	**4**
2	0.000			
3	0.047	0.000		
4	0.000	0.000	0.000	
Población	0.000	0.000	0.000	0.000

Conclusiones

Los resultados presentados en este trabajo avalan la necesidad de elaborar políticas públicas que superen la visión de una distribución de ingresos única y que se empiece a actuar considerando que en una misma población coexisten varias distribuciones de ingresos a la vez.

Los resultados del análisis exploratorio realizado en este estudio indican que es posible aplicar técnicas de agrupamiento con datos longitudinales para identificar distribuciones condicionales de los ingresos personales en una población. Al aplicar la técnica a datos de panel de la Encuesta Nacional de Hogares (ENAHO) del Perú entre los años 2015-2018, se encontró que es posible distinguir cuatro distribuciones condicionales de ingresos claramente distintas, tanto en sus centroides como en los parámetros definitorios de media, varianza, asimetría y curtosis. En todos los casos, se encontraron diferencias entre las distribuciones condicionales y también con respecto a la distribución no condicional de ingresos de toda la población.

Como futuros desarrollos que podrían surgir a partir de los resultados de este estudio exploratorio están, por un lado, el de encontrar nueva evidencia empírica con datos longitudinales de otros países que apoyen este tipo de resultados. Mientras que, por otro lado, para futuras investigaciones queda pendiente identificar los sectores productivos y ocupaciones a las que estarían ligadas cada una de estas distribuciones de ingresos.

Agradecimientos

Este trabajo fue elaborado en el marco del Proyecto de Investigación VRIDT-UCN, titulado: “Distribuciones de Ingresos de los Hogares Individuales”.

Abstract

There is great pressure on farmers worldwide to maximize their economic and social benefits from the land they own, while facing land degradation and desertification. Sustainable land management is the key answer to these challenges and is land management through which human society aims to improve agricultural production, living conditions and ecosystems. In order to integrate irrigation and drainage works in an integrated management of natural resources, it is necessary to establish a set of measures to coordinate and support the factors involved in this field, especially end users (farmers, organizations of water users for irrigation, specialists in the field of land improvements). The structure of agricultural land exploitation in Romania has not changed significantly during the last decade, maintaining the same fragmentation and the same extreme polarity, major impediments to increasing the competitiveness of the agricultural sector. Romania suffers from the most acute problem of fragmentation of agricultural property among all the countries of the European Union and has an average size of exploitation similar to Malta or Cyprus, island countries with much smaller agricultural areas than Romania.
The use of agricultural land is determined by the overall evolution of human society, mainly by the demand-supply ratio of agricultural products that manifests itself on the market. The demand for agricultural products is determined by the needs of final consumer or industrial consumption. These needs are directly related to the number of population, its purchasing power and the degree of integration and development of agricultural raw materials processing industries. The supply of agricultural products is determined by the area in the agricultural circuit and the level of yields per hectare. The use of agricultural land is influenced by the agro-climatic conditions, as well as by the economic, financial, demographic, technical and technological conditions existing in a country at a given time. An analysis of the evolution of land use categories in Galati County shows that the agricultural area of Galati County is 351779 ha, of which 289581 ha of arable, 40914 ha of natural pastures, 700 ha of natural finesse, 19521 ha of vineyards and 1763 ha of orchards and fruit nurseries.
Globally, the effects of desertification are increasingly being observed as a consequence of long periods of drought and the reduction of fertile areas that have led to a decrease in crop production. In Galati County, the phenomena of excessive drought affected large areas of agricultural land in 2015 and 2020. Irrigation facilities in Galati County represent 41.4% of the arable land of the county, of which 33,171 ha were rehabilitated, which represents 22.8 % of the arranged surface and 9.4% of the arable surface of Galati County.

Keywords: Land Fund, Land Improvements, Irrigation

Introduction

In Romania, rural areas occupy almost 90% of the territory and count about 50% of the total population. To achieve a real picture of the agricultural development, it is necessary to analyze the evolution of the land fund structure and especially the structure of arable land, in order to identify trends and their medium and long-term effects.

Cite this Article as: Marius Daniel NICULA, Dumitrache Bogdan BRATOVEANU, Petre Adrian LIPTAC and Silvius STANCIU “Land Fund Structure and Land Improvement works In Galati County” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The change in the type of ownership of agricultural land and the formation of a new organization structure of agricultural producers, have generated excessive fragmentation of agricultural land, the formation of a large number of individual subsistence farms, a restriction of productive services for agriculture (irrigation, fertilization , mechanization, etc.) and a significant depreciation of the productive quality of the land.

Romania has an important land wealth, 63.3% of the country's surface has an agricultural destination and is structured by categories of use (arable, natural pastures and hayfields, vineyards and orchards), but but also under the influence of natural factors and economic and social-historical facts (people's needs and concerns, tradition, etc.).

The evolution of agricultural productions is closely related to the changes that have taken place in the ownership structure of the land fund and of the other means of production, as well as of the climatic variability. The predominantly cereal character of the production structure represents a negative aspect of Romanian agriculture. The share of cereals in the region is high, even if the crop does not have favorable land and climatic conditions for the development of those species.

The ultimate goal of irrigation and drainage development is to improve agricultural production, increase rural incomes and minimize the risks posed by periods of drought. Irrigated agro-ecosystems tend to maximize production in the areas they occupy, but with proper management, they can provide other services such as erosion control by terracing, flood retention, sediment retention. The economic value of these services may in some cases exceed the value of the crops served by land improvement systems and the improvement of ecosystems.

Materials and Methods

The materials that formed the basis of this paper are information obtained through the usual means, respectively: newsletters, statistical yearbooks, statistical briefs. The research methods used in this study are: basic research (pure or basic) and evaluative research.

The preliminary documentation aimed to identify and study the general information sources and, subsequently, the specific information sources, in order to determine the characteristics of the researched area. For this purpose, the databases and statistical bulletins of the National Institute of Statistics of Romania were consulted, in order to observe the time series of some indicators relevant for research, as well as data provided by the County Directorate of Statistics.

Results and Discussion

Land fund structure

The way in which Law 54/1998 was implemented and especially the delay with which it was achieved, generated a series of effects (disturbing factors), respectively:

- fragmentation of agricultural land;
- the non-correlation of the application of the Land Fund Law with the appearance of the land market, this appearing late, in 1998 (Law 54/1998 on the legal circulation of lands);
- failure to ensure, together with the right of ownership over the lands, the adequate means for carrying out the agricultural works.

The agricultural surface of Galați County is 351779 ha, of which 289581 ha are arable, natural pastures 40914 ha, vineyards 19521 ha and orchards and fruit nurseries 1763 ha. The agricultural area of Galati County is structured by categories of use as follows:

Table 1: The structure of agricultural field of Galati County

Specification	ha	%
Agricultural area	**351779**	**100**
Arable land	289581	82,3
Natural pastures	40914	11,6
Vineyards	19521	5,6
Orchards and fruit nurseries	1763	0,5

Source: data processed according to the records of the Galati County Department of Agriculture

Figure 1: The structure of the land fund in Galati County

From table 1 and figure 1 it results that compared to the agricultural area, the arable land represents 82.3%, the vineyards and trees plantations 6.1% and the pastures and hayfields 11.6%.

The main crops that occupy large areas in the county are: grain cereals (wheat, rye, barley, barley, oats, corn grains), technical plants (soybean, sunflower, rapeseed, mustard, sugar beet, tobacco, broom sorghum), legumes (beans, peas), potatoes, vegetables (tomatoes, onions, cabbage, peppers, roots), melons and fodder plants.

At the level of Galati County, viticulture occupies 19521 ha, and fruit growing 1763 ha. Vegetable growing is one of the representative agricultural sectors for Galati County, given the existing tradition and the potential that must be capitalized more. Considering that in Galati County there is one of the largest vegetable basins in the country, vegetable growing can become a key point for the development of Galati County in the regional context.

Land Improvement Works

Facilities for irrigation in the complex (irrigation, drainage, combating soil erosion) represent 41.4% of the arable land of the county, of which 33171 ha were rehabilitated, which represents 22.8% of the developed area and 9.4% of the arable area of Galati County.

The areas arranged for irrigation, proposed for public utility in 2021 are presented in table 2.

The rehabilitation actions of the irrigation systems "Câmpia Covurlui", "Terasa Tecuci Nicoreşti" and "Brateşul de Sus" were carried out in the period 2015-2020 by the National Company for Land Improvements, Galati Territorial Branch. In parallel with these activities, the Associations of Water Users for Irrigation were set up, which took over the patrimony for free use of irrigation arrangements for use in irrigation campaigns, a situation that was reflected in the average and total productions of irrigated crops and to which watering was applied during the growing season.

Globally, the effects of desertification are increasingly being observed as a consequence of long periods of drought and the reduction of fertile areas that have led to a decrease in crop production.
In Galati County, the phenomena of excessive drought affected large areas of agricultural land in 2015 and 2020. In 2015, a state aid scheme was established by OUG 45/2015 to compensate for the damages caused by the meteorological phenomenon of severe drought during April-September 2015. In 2020, a state aid scheme was established by OUG 148/2020, granted to agricultural producers who set up crops in the autumn of 2019, affected by the pedological drought.

In accordance with the National Strategy for reducing the effects of drought in the short, medium and long term, the strategy at the level of Galati County has as main objectives the following:

- rehabilitation of the existing irrigation arrangements and realization of new arrangements through investments of rehabilitation of the arrangements from the ANIF administration and extension of the irrigation surfaces in the meadow areas (Prut and Siret) which involve low electricity consumption;
- restoration of anti-erosion plantations that have the role of fixing and defending the lands affected by surface erosion and of limiting soil losses in case of torrential rains.

For Galati county, the arrangements for irrigation, drainage and combating soil erosion are presented in table 3.

The need to carry out the proposed rehabilitation works is imposed by the fact that the irrigation facilities in the complex were put into operation until 1990 and were subject to destruction due to both climatic factors and bad intentioned people.

Table 3 : The situation of arrangements for irrigation, drainage and combating soil erosion in Galati County

3 OUAI	2840	-	-
ANIF	3243	-	-

Source: data processed according to the records of the Territorial Branch of Land Improvements Galaţi

The expected economic effects as a result of the proposed investments are:

- reduction of water losses on canals and plots, as well as reduction of electricity consumption for pumping irrigation water to hydrants;
- waterproofing and reduction of water losses by infiltration;
- rehabilitation of the network of buried pipes, supply channels and pumping stations;
- extension of irrigation areas in meadow areas (Prut and Siret), which involve low electricity consumption (only one pumping stage).

The role of anti-erosion plantations is to fix and protect the lands affected by surface erosion, to regulate surface runoff, to limit soil losses in case of torrential rains.

The favorable effects of anti-erosion plantations are:

- reduction of water evaporation from the protected surface;

- more vigorous development of neighboring agricultural crops;
- acceleration of infiltrations and stopping the phenomena of soil transport by water.

Excessive drought and persistence over time, accompanied by high temperatures cause crop losses to non-irrigated crops.

Agricultural producers, legal entities or natural persons do not have at the beginning of the agricultural year information or warnings on the forecast of drought phenomena (pedological and atmospheric) so that they can make appropriate decisions regarding the use of seeds of drought-resistant varieties or the application of specific technologies.

Some agro - meteorological information is brought to the attention of agricultural producers only by radio - TV means, but it is not accompanied by technical measures and actions to be applied by agricultural producers in the crop program.

In very dry areas, where the water deficit in the soil is permanent, it is necessary to apply specific technologies. Thus, the soil works are performed differently, as follows:

For autumn crops:

- plowing is performed at depths of 20 - 25 cm, or the hard disk is used;
- the preparation of the germination bed and the sowing is done in maximum 2-3 days to avoid water losses from the soil.

For spring crops:

- the works of plowing or discussing with the hard disk must be executed since autumn or in the winter windows;
- if the land has remained uncultivated since autumn, it is indicated, in the spring, to carry out the discussion at 15 - 20 cm and immediately, the preparation of the germination bed and the sowing.

Given that agricultural producers have high-capacity tractors and specific equipment, these works can be carried out (plowing, prepared germination bed, basic fertilizer, pre-emergent herbicide and sowing) in the **"minimum tillage"** system.

To avoid water loss from the soil, other mechanical works are required:

- weeds or herbicides to control weeds and destroy the crust that appeared on the soil surface;
- for the protection and sustainable use of soils, in Galati county are required annually soil quality monitoring studies carried out by the Office of Pedological and Agrochemical Studies - a specialized institution in the field.

Execution of mechanical works on very dry lands, requires the renewal of the fleet of tractors and agricultural machines with high-performance equipment to perform mechanical works of the soil with few passes on the same surface.

Compared to those presented above, it is proposed the elaboration of pedological studies to substantiate projects for the realization of pedo-ameliorating works of the soils, with execution until the end of 2021 (table 4).

Table 4: Pedo-ameliorating works of the lands on the cadastral territory of Galaţi

Works category	Arable -ha	Pastures - ha	Total - ha
Dreinage	48653,57	401,43	49055
Irrigations	145167,01	486,99	145654

Conclusions

The phenomenon of pedological drought seems to intensify in the coming years due to geographical position and major climate change. Romania will need firm strategies in terms of mitigating the destructive effects of this meteorological phenomenon. These strategies can materialize in practice through close collaboration between decision makers and the population that has become aware that the declines in animal and plant production resulting from excessive drought not only affect their own households, but lead to lower living standards and well-being of

the whole society. A clear vision of the strategy for land improvement on agricultural land could help prevent serious problems with the emergence of the phenomenon of pedological drought.

The developing plan of the Galati County territory, elaborated in 2011 by the Galati County Council, provides the following objectives regarding the land fund and the arrangements for irrigation:

- capitalization of uncultivated lands that have pedological potential for at least one of the types of crops (agriculture, viticulture, fruit growing or vegetable growing).
- rehabilitation of irrigation systems, drying and combating soil erosion.
- ecological reconstruction of soils,
- arranging and maintaining buffer zones cultivated with grass, grass corridors or ponds and erosion dams.

Abstract

Mobile wallet, along with debit/credit cards and internet banking, are technologies and mean widely used for digital payment. While neighboring countries advanced in the adoption of mobile wallet for digital payment, Malaysian is considerably "infant" as this technology is not extensively used. This paper reports the outcome of the research that investigated the users' behavioral intention and the determinant to adopt mobile wallets as digital payment platform in a selected locality in Malaysia. In establishing the study, a research model built upon three basic constructs of Unified Theory of Acceptance and Use of Technology 2 (UTAUT 2) and previous relevant research models on factors influencing behavioral intention on mobile wallet was proposed. Adopting the convenience sampling technique, the online questionnaire had been administered to 384 respondents. The 327 returned questionnaire had been examined and the 315 valid questionnaire were brought into analysis. Both SPSS and SmartPLS were used for descriptive analysis, internal consistency reliability analysis, indicator reliability analysis, convergent validity analysis, discriminant validity analysis, coefficient of determination (R2) analysis, path coefficients analysis and hypotheses testing where appropriate. The results revealed that Hedonic Motivation is the strongest and most crucial factor influencing the intention to use mobile wallet. The Perceived Risk, Perceived Security and Perceived Trust have significant influence on behavioral intention on mobile wallet usage.

Keywords: Behavioural intention, effort expectancy, facilitating condition, hedonic motivation, perceived risk, perceived security, perceived trust, mobile wallet

Introduction

As information technology infrastructure become mature, businesses nowadays are conducted online and in digitally manner. Businesses adopted online payments methods such as internet banking, electronic cards (debit and credit), mobile banking and also mobile payment such as mobile wallet (Sarika and Vasantha, 2019; Bezhovski, 2016; Wang et al., 2019; Pandy and Crowe, 2017). With such online payment facilities, businesses may reach users 24/7 without border.

The mobile wallet technology allows users to perform the transaction virtually and easily in both in-store and remote place (Liébana- Cabanillas et al., 2018). Since the first day of its establishment, mobile wallet technology was widely used by people worldwide for digital payment. It is reported that countries like China and India (PwC Malaysia, 2018)

have an extensive use of mobile wallet for performing online transaction and digital payment. The use of mobile wallet for making online payment is growing for its easy to use feature.

In Malaysia, a variety of mobile wallet types are available for the users. The four mobile wallet types are open, semi-open, semi-closed as well as a closed wallet (Kumar and Sharma, 2019; Rao, 2015). In Malaysia, despite the existence of providers of mobile wallets such as AEON wallet, Maybank Pay, Grabpay and Gift voucher (Farhan Gazi, 2020), the use of mobile payment is considerably new and is not frequently being applied (Yeow et al., 2017). People prefers former methods and reluctant to exchange their credit or debit cards' role with the use of mobile wallet in making payment (Aydin and Burnaz, 2019). The Star (2019) reported that only 8% of Malaysia citizens are currently using mobile wallet to make online payment whereas Muller (2020) stated that 67% of Malaysians conducted their transaction using credit card and online banking.

It is learnt from the reports Malaysians prefer online transaction but less prefer to use mobile wallet. This issue is hypothesized to be related to the behaviour of the consumers. Triggered by this hypothesized issue, the study investigates users' behavioural intention and the determinant in adoption of mobile wallets as digital payment platform. The two research questions devised for the study are the main factors that determine behavioural intention towards mobile wallets among users and the extent of effort expectancy, facilitation condition, hedonic motivation, perceived security, perceived risk and perceived trust influence the use of mobile wallet behavioural intention.

The remaining sections of this paper are arranged as follows. The literature review comes to discuss the background that surround the issue tackled in the study. Section #3, i.e. the hypotheses development and research model justifies the formulated hypotheses for the study. The methodology that the research adopt is justified in section #4. Next section presents the finding of the research and section #6 follows to discuss the finding. Section #7 concludes the paper.

Literature Review

Digital economy built upon digital computing technologies. The digital economy lets businesses transformed into e-commerce and e-business. Digital economy stands as part of economic output that derived solely or primarily from digital technologies with a business model (Bukht and Heek, 2017). As digital economy grows rapidly since beginning of this century, the way the business is conducted transforms significantly in which technological-based means are adopted in many business dimensions.

One of the business area where computing technologies is widely adopted is payment system. In digital economy, the cash transactions were not preferred and the transaction is made using electronic money (Mohanad Faeq Ali et. al. 2019). The use of electronic payment system is the main strength of e-commerce and the most vital aspect of digital business (Bezhovski, 2016; Maurya, 2019). Due to advantages such as adequate payment infrastructure and practical use, electronic payment become the preferred mean for making payment for goods and products purchased.

There are various kind of digital payment methods available for consumers to choose from. One of the among earliest method was debit/credit cards (Xiao, Hedman and Runnemark 2015). Currently, internet banking system (Zheng et. al. 2009) is widely used. As mobile technology advances, the contactless cards and mobile payment (Chae and Hedman, 2015; Ozcan and Santos, 2014) quickly adopted by consumers for the purposes making payment. The variety of methods and instruments offer consumers with flexibility in enabling the electronic payment.

Mobile wallet is one of the mobile payment instruments that is used for purchasing goods and services in easier and more convenient manner. Mobile wallet originates from the digital wallet (Doan, 2014) in which it stores credit information on the cloud. Bosamia (2017) and Singh et al. (2017) stated that mobile wallet is a virtual wallet that exists in the smartphone where the money is stored in virtual form. Mobile wallet as an application software on smartphone serves as a digital container to store information like payment and loyalty cards, tickets, receipts and vouchers (GSMA 2012). With mobile wallet, cashless and/or cardless transaction can be established. Mobile wallet has both software and hardware enable the use of credit or debit transaction with smartphones.

Mobile wallet is preferred by smartphone users for many reasons. It enables mobile users to be more accessible to financial services. It also facilitates the users in using their credit or debit cards virtually for financial transactions like paying bills, shopping, booking tickets, fund transfer and etc. (Singh et al., 2017). With pre-installed application or program and tap-to-pay procedures, mobile wallet enables fast monetary transaction for practical usage.

With respect to the extent of usage, literature indicates the classification for mobile wallet. Generally, mobile wallet is classified into four classes namely open, semi-open, semi-closed and closed wallets (Sardar, 2016; Rana 2017; Alaeddin et al., 2018). These four types can be either based on the ability to reload, connected with the bank or having the option where money can be withdrawn (Wadhera et al., 2017). The open wallet enables transactions at any in-store and online purchase. Example of open wallet are Paypal and Maybank Pay (MAE wallet) (Oh, 2018; Farhan Gazi, 2020). The semi-closed wallet enables consumers to purchase goods and services from registered stores. Grabpay and *Touch 'n Go* are examples for semi-closed wallet (Farhan Gazi, 2020; Chew, 2019; Birruntha, 2019). Lastly, the closed wallet is used exclusively for the purchases in the merchant's premise or company such as Golden

Screen Cinema and Gift vouchers (Alaeddin et al., 2017). More examples for closed, semi-closed, semi-opened and open wallets are available both in the published literature and internet for references.

Studies on mobile wallet are extensive as the researchers studied mobile wallet from diverse perspectives. Far earlier, Shin (2009) validated a comprehensive model of consumer acceptance in the context of mobile payment. Amaroso and Magnier-Watanabe (2012) proposed a comprehensive model integrating eleven key consumer-related variables affecting the adoption of mobile and identified the case of the successful adoption mobile wallet in Japan. Seetharam et al (2017) investigated the key factors that influence the acceptance of mobile wallet in Singapore. Zhang et al, (2018) examines the factors that influence both the technology acceptance and actual usage aspects of mobile payment adoption from the perspective of the general systems theory. Chawla and Joshi (2019) examined the factors that influence a consumer's attitude and intention to use mobile wallets using a sample representative of Indian users. In addition to this, Husnil et al (2019) had examined the factors of hedonic motivation and social influence on intention to use e-money in Indonesia in which they found that both factors are crucial in accelerating the intention on e-money usage. Singh and Sinha (2020) measured merchant's intention to use a mobile wallet technology. A latest one examines the effect of perceived risk, government support, and perceived usefulness on customers' intention to use e-wallet during COVID-19 outbreak (Aji, Berakon and Md Husin, 2020). The huge studies on mobile wallets were reported in the literature reflecting a huge variety of related dimensions of mobile payment.

The studies reported above have been conducted in several countries including Malaysia. In Malaysia, the use of mobile wallets is growing as PwC Malaysia (2018) found that only 22% of people tend to adopt e-wallet services and most cases that use e-wallet are mainly in e-commerce. Therefore, it is acknowledged that if compared to Indonesia, e-wallet adoption in Malaysia is still in its infancy (Aji, Berakon, Md Husin 2020; PWC, 2018). Following Chwah, et al. (2018), even though most people own smartphone and the mobile wallet has preliminary existed, the use of cash and card payment are still in a higher demand in making purchase especially in the physical store such as mall, groceries or stalls.

The less usage of mobile wallet facility to make payment compared to its neighbouring countries as reported invites a research effort. In establishing this research, the combination of perceived trust, perceived security and perceived risk with three constructs that initially exist in UTAUT2's structure (effort expectancy, facilitating condition hedonic motivation) is made. The goal of the combination is to allow a research that is comprehensive in nature with expectation to yield a strong justification in its finding.

Hypotheses Development and Research Model

The construct of hypotheses for the research reported in this paper are as follows.

Behavioural Intention

Behavioural intention is a degree in which an individual has conveyed a mindful plan regarding the decision of whether or not to perform a definite future behaviour (Venkatesh et al., 2012). Many studies have used this construct to study the intention towards adopting the technology like mobile payment (Thakur and Srivastava, 2013; Phontanukitithaworn et al., 2015; Mehdi et al., 2018) and for mobile wallet (Patel, 2016; Hanudin Amin, 2009; Kafsh, 2015; Singh et al., 2017). Behavioural intention is important in order to identify the users' intention to use something new since in Malaysia, mobile wallet is considered new and still at the growing stage of usage as compared to other advanced countries. This is to measure the level of users' intention to use mobile wallets as part of mobile payment in making the purchase to become easier and convenient.

Effort Expectancy

Venkatesh et al. (2003) defined effort expectancy as the level of easiness when using any related systems. Users will show more inclination to use the mobile wallet only if it is easy to be used. This is because, if the system is using user-friendly technology, it can surely gain high acceptance, thus, being adopted by users as they will not feel any hassles or putting a lot of effort in using this mobile wallet (Park and Ohm, 2014). Recent studies by Megadewandanu et. al. (2016) and Singh et. al. (2019) have been shown that effort expectancy has a significant or positive influence on the intention in the use of mobile wallet. This study proposes the following hypothesis for effort expectancy.

H1: Effort expectancy has positives influence on users' intention to use mobile wallet

Facilitating Condition

According to Venkatesh et al. (2003), facilitating condition is the degree in which an individual knows and believes that both organizational and technical infrastructure exist to support them in using the system. When users have insight about technologies or a mobile wallet which is able to give them support in using the application, they will become more willing to use the mobile wallet and feel not afraid if they will misuse it. Previous studies found that facilitating condition has positive effect towards the behavioural intention in using mobile wallet (Chawla and Joshi, 2019;

Megadewandanu et al., 2016; Patel, 2016; Madan and Yadav, 2016). In this study, the following hypothesis related to facilitating condition is proposed.

H2: Facilitating condition has positive influence on users' intention to use mobile wallet

Hedonic Motivation

Venkatesh et. al. (2012) defines hedonic motivation as a feeling of excited or pleasure which resulted from the use of technology. It is one of the important roles that is needed in order to identify whether users will accept and use it or not (Brown and Venkatesh, 2005). The technology will not be useful if users are not feeling interested or excited about the device. When they have an interest and feel excited, it will increase their intention to use mobile wallet. The studies by Megadewandanu et al. (2016) and Morosan and Defranco (2016), found that this determinant has a positive influence on behavioural intention to use mobile wallet. Relating to this determinant, this study hypothesise that;

H3: Hedonic motivation has positive influence on users' intention to use mobile wallet

Perceived Risk

Risk can be defined as the uncertainty such as the severity of certain occasions as well as the consequences from the outcome of action conducted due to respect to human value (Aven and Renn, 2009). As the behavioural intention of the mobile wallet involves some degree of uncertainty, it is believed that perceived risk is fused as a direct determinant of behavioural intention to adopt the technologies. According to a study by Singh et. al. (2019) and Madan and Yadav (2016), when perceived risk is decreasing, the intention to adopt a mobile wallet is increasing simultaneously. This study adopts the perceived risk and the construct the following hypothesis.

H4: Perceived risk has negative influence on users' intention to use mobile wallet

Perceived Security

Perceived security is defined as the level of confidence that the users have regarding the security system (Law, 2007). The mobile wallet had opened up many different and new risks on security such as the risk of smartphones which might be stolen, damaged or even lost (Chari, et al., 2001). When this happens, the security of information stored in the mobile wallet is crucial to be protected. Studies show that perceived security consist of a positive influence on behavioural intention to use a mobile wallet to make a purchase (Chawla and Joshi, 2019; Kafsh, 2015; Shin, 2009; Seetharaman et al., 2017). When the users are confident that mobile wallet is able to secure their personal data and information, many will be willing to use mobile wallet. On perceived security, the following hypothesis is proposed.

H5: Perceived security has positive influence on users' intention to use mobile wallet

Perceived Trust

Trust refers to the concept of willingness to be taken from the actions of other persons or a third party (Redhwan Mohammed Abdullah Al-Amri et. al., 2016). The trust factor has been found to be useful and was included in previous studies related to mobile wallet (Shaw, 2014; Chawla and Joshi, 2019; Shin, 2009). Following Yan and Yang (2014), trust on mobile payment allows positive expectation regarding its system. When users doubt that this mobile wallet has a high security of their information, it will be difficult for them to increase their intention in using the mobile wallets. Studies by Chawla and Joshi (2014) show that trust really plays an important role in influencing the behavioural intention of mobile wallet in India. That is why, trust is important to be included in this study. In this study, the following hypothesis is proposed pertaining to trust.

H6: Perceived trust has positive influence on users' intention to use mobile wallet

The six variables with their respective hypothesis is gathered into theoretical model depicted in Figure 1. It is noted that these main variables were adopted from previous studies (Venkatesh et al., 2012; Megadewandanu et al., 2016; Singh et al., 2019; Aydin and Sebnem Burnaz, 2016; Chawla and Joshi, 2019) for better understanding of the users' behavioural intention on mobile wallet. It is expected that this model may help in clarifying the issue on users' behavioural intention on the technology in this research context.

Fig 1. Theoretical Model for Behavioral Intention to Use Mobile Payment System

Methodology

This research adopts the quantitative approach in order to identify users' behavioural intention on mobile wallet. The study setting was Shah Alam, the capital city of Selangor, Malaysia with 650,000 populations (Shah Alam City Council, 2019). The research instrument was questionnaire with eight (8) sections namely Demographic Profile, Behaviour Intention, Effort Expectancy, Facilitating Condition, Hedonic Motivation, Perceived Risk, Perceived Security and Perceived Trust and five (5) scales of Likert measurement. Upon pilot testing, the questionnaire was administered online to 384 respondents following convenience (non-probability) sampling. A total of 327 questionnaires were returned and 315 set of questionnaire were valid for analysis. Applying both SPSS Statistics Version 22 and also SmartPLS Version 3.0, the analysis techniques applied were descriptive, common method variance and structural equation modelling (SEM) with two steps modelling approach namely Confirmatory Factor Analysis (CFA) and structural model to examine the relationship between independent and dependent variables.

Result and Discussion

The result of statistical analysis using SPSS Version 22 and SmartPLS Version 3.0 includes the brief demographic profiles, internal consistency reliability, indicator reliability, convergent validity, discriminant validity, coefficient of determination (R2), path coefficients and hypotheses testing.

Demographic Profiles

Table 1 shows the simplified and brief characteristics of the respondents on mobile wallet. The survey had been responded by working professional (54.6%), student (34.6%), entrepreneur (2.5%), unemployed citizen (3.8%) and self-employed personnel (1.9%). With regard to mobile wallet usage, it is found that 182 (57.8%) respondents have never used mobile wallet to make payment and remaining 133 (42.2%) used it in store. On the choice of payment method, the descriptive analysis indicated that respondents less prefer mobile wallet or digital wallet as only 14 (4.4%) of respondent opted this option. The online banking is at higher preference among respondents with 68.9% (217) while use of credit/debit card for payment is preferred by 84 (26.7%) respondents. On the reason for using mobile wallet, respondents intended to use it mostly for shopping (199:63%), paying bills (95:30.2%), movie tickets (14:4.4%), booking for services and products (5:1.6%) and other purposes (2:0.8%)

Table 1: Demographic Result

Demographics	Options	Frequency	Percentage (%)
Occupation	Student	109	34.6
	Working Professional	172	54.6
	Entrepreneur	8	2.5
	Self-employed	6	1.9
	Unemployed	12	3.8
Mobile wallet usage in store	Yes	133	42.2
	No	182	57.8
Choice of payment method	Credit or Debit Card	84	26.7
	Online Banking	217	68.9

	Digital Wallet	14	4.4
Main reason	Shopping	199	63.0
	Paying Bills	95	30.2
	Movie tickets	14	4.4
	Booking	5	1.6
	Others	2	0.8

Internal Consistency Reliability

For testing the reliability and validity of the model used in the study, Confirmatory Factor Analysis (CFA) was used using SmartPLS software. All constructs under Effort Expectancy (EE), Facilitating Condition (FC), Hedonic Motivation (HM), Perceived Risk (PR), Perceived Security (PS), Perceived Trust (PT) and Behavioural intention (BI) were included. As depicted on Table 2, the measurement model was considered reliable as all item loadings (FC4, PerRisk1, PerRisk2, PerRIsk3, PerSec3, BI3 and BI4) below the arbitrary value of 0.7 were excluded. As for Average Variance Extracted (AVE) of each available construct were found to have acceptable range from 0.566 to 1.000 in which the value gained is more than the recommended AVE value that is 0.5. Lastly, the Composite Reliability (CR) of the study was also found to be in good range from 0.839 until 1.000.

Table 2: Item Loading, AVE and CR.

Factor	Items	Loadings	AVE	CR
Effort Expectancy (EE)	EE1	0.884	0.715	0.909
	EE2	0.807		
	EE3	0.861		
	EE4	0.827		
Facilitating Condition (FC)	FC1	0.875	0.664	0.855
	FC2	0.773		
	FC3	0.794		
Hedonic Motivation (HM)	HM1	0.874	0.751	0.900
	HM2	0.875		
	HM3	0.851		
Perceived Risk (PR),	PerRisk4	1.000	1.000	1.000
Perceived Security (PS)	PerSec1	0.825	0.596	0.815
	PerSec2	0.756		
	PerSec4	0.732		
Perceived Trust (PT)	PerTrust1	0.779	0.611	0.917
	PerTrust2	0.740		
	PerTrust3	0.751		
	PerTrust4	0.784		
	PerTrust5	0.785		
	PerTrust6	0.822		
	PerTrust7	0.809		
Behavioural intention (BI)	BI1	0.733	0.566	0.839
	BI2	0.718		
	BI5	0.748		
	BI6	0.808		

Discriminant Validity

The assessment of discriminant validity is established upon two well-known measures i.e. Fornell and Larcker's criterion (1981) and cross loading. As for first assessment, each AVE construct is generated and processed using SmartPLS built in algorithm. In Table 4, the bold element represents the square root of AVE results and the non-bold represents the inter-correlation value between each construct. It is noted that all the square root of AVE elements are higher than the other element construct. It implies that the result gained for discriminant validity meets the Fornell and Larker's criterion.

Table Error! No text of specified style in document.**: Inter-correlation Matrix (Fornell and Larker's criterion).**

	Behavioral Intention (BI)	Effort Expectancy (EE)	Facilitating Condition (FC)	Hedonic Motivation (HM)	Per Risk (PR)	Per Security (PS)	Per Trust (PT)
Behavioral Intention (BI)	**0.753**						
Effort Expectancy (EE)	0.427	**0.845**					
Facilitating Condition (FC)	0.315	0.55	**0.815**				
Hedonic Motivation (HM)	0.474	0.37	0.4	**0.867**			
PerRisk (PR)	-0.134	0.037	0.09	0.013	**1.000**		
PerSecurity (PS)	0.446	0.476	0.271	0.31	-0.044	**0.772**	
PerTrust (PT)	0.469	0.39	0.216	0.418	-0.123	0.627	**0.782**

Once the first assessment is established, the following assessment examines the indicators' loading of all construct correlations. The result for cross loadings also produced from SmartPLS algorithm process. Table 5 shows the result of cross loading that exists between the construct and indicators. Identical to Fornell and Larcker's criterion, the indicators loading must have higher value against their respective intended variables as compared to other variables. As indicated in Table 5, the loading of each block is higher than any other block within the same rows and columns. Therefore, this output confirms the cross loading measurement. Both reliability and validity tests that have been conducted on the measurement model achieve the satisfactory level. The result from the tests confirmed the indicators' validity to be used in the structural model.

Table 5: Cross Loading Output by Smart PLS

	Behavioral Intention (BI)	Effort Expectancy (EE)	Facilitating Condition (FC)	Hedonic Motivation (HM)	Per Risk (PR)	Per Security (PS)	Per Trust (PT)

Coefficient of Determination (R2)

The R2 value indicates that the amount of variance that contains in the dependent variable required to be explained by the independent variables. It implies that, when R2 has larger a value, it will increase the predictive ability of structural model. SmartPLS's algorithm is used to obtain the R2 value in this study. The SmartPLS's bootstrapping is used to help in generating the t-statistic as well as path coefficient value of the model. The bootstrapping had generated 500 samples from 315 cases. The result of structural model is presented in Figure 2 in which it displays Effort Expectancy, Facilitating Condition, Hedonic Motivation, Perceived Risk, Perceived Security and Perceived Trust are able to explain 38.1% of the variance in Behavioural Intention. The value of 0.381 makes the R2 for this study as average.

Figure 2: Result of Structural Model from SmartPLS's Bootstrapping

Path Coefficients

For the structural model used in this study, each path that connects six latent variables represent its own hypothesis. Therefore, based on the analysis on the structural model, it gives the researcher the ability to confirm or disconfirm each hypothesis made as well as to gain insight about the strength of the relationship that has existed between both dependent and independent variables in this study. Using the output gained from smartPLS algorithm and bootstrapping, the relationship between independent and dependent variables as well as their significant value were examined. Table 6 shows the path coefficient, t-statistics and significance levels for all hypothesis path used. The result of the hypotheses testing is discussed in the next subsection.

Table 6: Path Coefficient

Relationship	Standardized Coefficient	Standard Deviation (STDEV)	T Statistics (|O/STDEV|)	P Values
Effort Expectancy (EE) -> Behavioral Intention	**0.162**	**0.088**	**1.829**	**0.068**
Facilitating Condition (FC) -> Behavioral Intention	**0.046**	**0.066**	**0.703**	**0.483**
Hedonic Motivation (HM) -> Behavioral Intention	0.278	0.060	4.662	0.000
PerRisk -> Behavioral Intention	-0.121	0.044	2.751	0.006
PerSecurity -> Behavioral Intention	0.164	0.076	2.140	0.033
PerTrust -> Behavioral Intention	0.162	0.068	2.370	0.018

Hypotheses Testing

Assessment of path coefficient, t-statistics and significant levels is critical to reject or accept the proposed hypotheses. As indicated in Table 6, it is learnt that Behavioural Intention is influenced directly by Hedonic Motivation (β=278, t=4.662, $p<0.05$), Perceived Risk (β=-0.121, t=2.751, $p<0.05$), Perceived Security (β=164, t=2.140, $p<0.05$) and

Perceived Trust (β=162, t=2.370, p<0.05). As a result, hypotheses H3, H4, H5 and H6 are supported. Among these four variables, Hedonic Motivation is found to be the most crucial and significant factor in influencing the behavioural intention on mobile wallet in the context of this study. The behavioural intention is not influenced directly by Effort Expectancy (β=0.144, t=1.829) and Facilitating Condition (β=0.047, t=0.703) since the p-value is more than 0.05 while t value is less than 1.967. The insignificant p-value and t value lead to rejection of hypothesis H_1 and H_2

Table 4.14: Hypothesis results

#	Hypothesis Statement	Result
H1	Effort expectancy has positives influence on users' intention to use mobile wallet	Not Supported
H2	Facilitating condition has positive influence on users' intention to use mobile wallet	Not Supported
H3	Hedonic motivation has positive influence on users' intention to use mobile wallet	Supported
H4	Perceived risk has negative influence on users' intention to use mobile wallet	Supported
H5	Perceived security has positive influence on users' intention to use mobile wallet	Supported
H6	Perceived trust has positive influence on users' intention to use mobile wallet	Supported

Findings

Based on the result produced from statistical analysis and discussion that follows, it is learnt that Hedonic Motivation is a critical factor influencing behavioural intention to use mobile wallet by its solid merit. Other three factors i.e. Perceived Risk, Perceived Trust, and Perceived Security accompanied Hedonic Motivation as crucial in influencing behavioural intention on mobile wallet. This finding is aligned with Wong and Mo (2019), Madan and Yadav (2016), Fatimah et al (2019), Megadewandanu et al., (2016), Verkijika (2018) and Patil, Dwivedi and Rana (2017) and Sardar (2016) where they earlier found that Hedonic Motivation, Perceived Risk, Perceived Security and Perceived Trust as crucial factors for people's intention to use mobile wallet. Among the four variables, this study found that Hedonic Motivation stands as strongest and most significant factor. This finding matches Fadzil's (2017) study who had produced similar finding. Both Fadzil (2017) and this study are conducted in Malaysia. Therefore, up to this point of time, it can be reasoned that Malaysian people take HM as critical factor for their engagement in mobile wallet. The implication would be that service provider shall increase the entertainment in mobile wallet application to make it more appealing. Not only that, it also crucial to make sure a high security provided in the mobile wallet, thus, minimizing any potential risk. The service provider also might need to increase and build close relationship with consumer in order to increase their trust.

As hypothesized, Hedonic Motivation, Perceived Security and Perceived Trust have positive influence on behavioural intention while Perceived Risk has negative influence on behavioural intention to adopt mobile wallet. The result affirmed these four hypotheses. As a result, it is learnt that when all these first three factors increase, the users' intention to use mobile wallet would also increase. And, when the perceived risk decreases, the intention is increasing. As for Effort Expectancy and Facilitating Condition, the result of study contrasts with Singh et al. (2019), Dong (2018), Morosan and Defranco (2016), Patel (2009) and Slade et al. (2013) in which they found the significant relationship between these two variables and behaviour intention to use mobile wallet. In response to this discrepancy, it might be said that users will have high intention to use mobile wallet when the level of Hedonic Motivation, Perceived Security, and Trust are high due to its significant and positive relationship, and low Perceived Risk as it has negative influence on the intention on mobile wallet usage.

Conclusion and Future Research

This research aims at determining the state of consumers' intention to use mobile wallet as previous literature informed that in Malaysia, the level and rate of mobile usage is at infancy. Being triggered from this issue, this study attempt at examining the determinants or factor may influence the adoption of mobile wallet service. The theoretical framework consisting of six determinants (Behavioural Intention, Effort Expectancy, Facilitating Condition, Hedonic Motivation, Perceived Risk, Perceived Security, Perceived Trust) gathered from established literature was proposed. Upon the analysis, it is found that the Hedonic Motivation, Perceived Risk, Perceived Security and Perceived Trust are the main factors positively affect users' behavioural intention on mobile wallet with Hedonic Motivation as the

strongest predictor. The other two predictors i.e. Effort Expectancy and Facilitating Condition have negative affect and thus rejected as they insignificant predictors.

Despite the intended objectives had been achieved, this study has some limitations in its locality and sampling in particular. Enhancement in future research can be made in the locality to include wider areas or all capitals in Malaysia at once or individually. Definitely this will involve larger sampling. By remaining its flavour, another potential research on this topic is examination about the intention of different the groups of citizen such as M40 and T20 in adopting the mobile wallet facility. The individual research effort can be accumulated to allow the pattern analysis of consumers' intention to use mobile wallet in Malaysia.

Abstract

The article is devoted to the study of ways to improve the foreign economic activity of large industrial regions of Russia. The authors describe the main factors hindering the development of export potential and reveal the tools for solving this problem. The article presents the forecast of the development of foreign economic activity of the Chelyabinsk region for the period up to 2035, compiled by the authors, using the methods of expert assessments and economic and mathematical modeling, in three versions - conservative, basic and target. This forecast was compiled by the authors taking into account the main scenarios of the socio-economic development of Russia and fully takes into account the specific features of the development of the Russian and regional economies. The authors propose sectors of the economy that are promising for the expansion of foreign trade and give forecasts for the development of the region's export potential.

Keywords: Regional Economy, Foreign Economic Activity, Export Operations, Marketing Strategies for The Development of The Region.

Introduction

The development of foreign economic activity of the regions of Russia has a positive effect on the rates of their economic growth, overcoming narrow product specialization and forming the prerequisites for the formation of new export industries. The stated topic is especially relevant for the economies of large industrial regions of Russia of the raw material type, experiencing serious crisis and post-crisis trends. The foregoing determined the relevance of the research topic and the choice as a subject of study of the foreign economic activity of the Chelyabinsk region as one of the large industrial regions of Russia, which is in dire need of the development of the export of its goods and services.

Results and Discussion

Currently, in the commodity structure of the region's exports, the priority remains the export of ferrous and non-ferrous metals, accounting for more than 85% of total exports, as well as mechanical engineering products - more than 6%, fuel and energy products - slightly less than 2%, chemical products - 1.7 %, food products and agricultural raw materials - 1.5% (Foreign trade statistics, 2020).

As shown by the study, the main factors constraining the development of the region's foreign economic activity in recent years are:

Cite this Article as: Irina Y. OKOLNISHNIKOVA, Antonina I. UKHOVA, Margarita D. OKOLNISHNIKOVA and Mark S. ANASTASOV "Development Scenarios of Foreign Economic Activity of Large Russian Industrial Regions (On the Example of The South Urals)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- weakening of the competitive positions of enterprises due to the raw materials orientation of exports;
- insufficient government regulation of foreign trade.

According to the authors, the tool for solving this problem is an effective state policy in relation to foreign economic activity, based on:

- strengthening the regulation of foreign trade;
- tightening control over the quality and quantity of goods crossing the border;
- attracting foreign investment;
- creation of optimal conditions for domestic exporters;
- support for export-oriented high-tech industries.

Based on these factors, the authors have compiled a forecast for the development of foreign economic activity of the Chelyabinsk region for the period up to 2035 in three options:

1. Conservative option - developed on the basis of a conservative assessment of economic growth rates, taking into account the continuation of sanctions by the US and the EU, which means maintaining limited access to the world capital market and the presence of counter-sanctions from Russia.
2. Basic option is based on conservative trajectories of changes in external and internal factors of economic development while maintaining the existing efficiency of resource use.
3. Target option - based on the achievement of target indicators of socio-economic development under conservative external economic conditions.

The main forecasting methods were the methods of expert assessments and economic and mathematical modeling. When forming forecasts for the development of foreign economic activity of the Chelyabinsk region, the main scenarios of the socio-economic development of Russia were taken into account, presented in table 1 (Russia has been offered three scenarios of socio-economic development in the long term - conservative, innovative and targeted (forced), 2020; Federal State Statistics Service, 2020).

The scenarios for the development of foreign economic activity developed by the authors take into account the following features of the development of the Russian and regional economies:

1. Moderate growth rates of GDP and industrial production in all scenarios of Russia's economic development, except for the accelerated one, with the modernization of the energy resource complex, the introduction of energy and resource saving technologies, the development of transport infrastructure, which will ensure the preservation of the traditional fuel and raw materials export potential.

2. Formation of a competitive sector of civil high-tech industries and the knowledge economy (including through increased funding for scientific research from non-state sources and technology transfer) in the case of moderately optimistic or forced scenarios, which will increase the weight in the structure of exports of high-tech products, science-intensive and intellectual services.

3. Increasing the export potential of the transport infrastructure serving international transport, the tourism industry.

4. Development of the knowledge economy.

5. Expansion of domestic investment and consumer demand, growing faster than GDP, which increases the priority of solving the problems of import substitution.

6. Increasing the competitiveness of industry, agriculture, services, as well as the implementation of the National Entrepreneurial Initiative, simplifying the business environment, facilitating the existing export procedures, which will cause an increase in the number of exporters while diversifying the export structure.

7. Formation of a national export support system based on financial, organizational, marketing, information, foreign trade and political and diplomatic tools to strengthen Russia's position in world markets.

Table 1. Russian GDP growth rate per year, %

Development scenario name	2021-2025	2026-2030	2031-2035
Conservative	2,7	2,9	2,6
Basic	2,6	2,9	3,4
Target	2,9	3,6	4,0

Taking into account the current state and expected dynamics of the listed factors of competitiveness, the sectors of the Russian economy that are promising for the expansion of foreign trade are:

- the fuel and energy complex (62% of total exports, 34.5% of non-primary exports), where Russia is the leader in reserves, production, and export of mineral fuel (oil, gas, coal) and products of its processing;
- metallurgical complex (7.5% of total exports, over 12% of non-resource exports) with a high supply of raw materials (nickel production, lead mining), affordable cost of energy resources (aluminum production) and unique technologies (titanium production);
- agro-industrial complex (4.5% of total exports, 8% of non-primary exports), characterized by an increase in the production of primary agricultural products due to a variety of natural and climatic zones, supply of fresh water, large areas of agricultural land and a rich raw material base for the production of mineral fertilizers;
- transport complex (3.5% of total exports, 6.5% of non-primary exports), which is an important element of international transport corridors; in addition, certain Russian technologies in this area are also competitive - space technologies, large-size air transportation, icebreaking operations, etc.;
- production and processing of precious metals and stones (over 2.5% of total exports, 3.5% of non-resource exports), characterized by their large reserves and rich traditions of jewelry;
- the military-industrial complex (2.5% of total exports, 4.5% of non-resource exports), where Russia ranks second in terms of arms exports;
- petroleum and gas chemistry (over 2% of total exports, 4% of non-resource exports), characterized by high production rates (1st place), moderate prices for energy resources and low environmental costs;
- the tourism sector (2% of total exports, 4% of non-resource exports), based on a variety of natural and climatic conditions and cultural and historical monuments;
- transport engineering, including the production of components (1.5% of total exports, about 3% of non-resource exports), where Russia is successful in the production of helicopters, rocket and space technology and jet engines;
- timber industry complex (about 2% of total exports, over 2.5% of non-resource exports), which has the largest reserves of industrial wood, moderate prices for energy and material resources, low environmental costs;
- nuclear complex - from uranium mining to the production of equipment for nuclear power plants and services for their operation (over 1.5% of total exports, more than 2% of non-resource exports) with a developed scientific and production base, unique technologies and developments, as well as extensive experience in successful implementation projects;
- IT technologies (1% of total exports, 2% of non-primary exports) with high dynamics of growth in the world market, the presence of highly qualified personnel in Russia and successful developments;

– power engineering, including the construction and operation of electric power facilities (0.3% of total exports, 0.6% of non-resource exports), characterized by the growing capacity of the world market, in which Russia is the leader in terms of facilities commissioned abroad.

The forecasts of foreign trade turnover, export and import of goods and services developed by the authors are presented in Figures 1-3.

Fig. 1. Scenarios for the development of the foreign trade turnover of the Chelyabinsk region until 2035, million dollars

Fig. 2. Scenarios for the development of export of goods and services of the Chelyabinsk region until 2035, million dollars

Fig. 3. Scenarios for the development of imports of goods and services of the Chelyabinsk region until 2035, million dollars

The main parameters of the baseline scenario for the development of the region's foreign economic activity until 2035 are:

- an increase in the value of exports by 2.2-2.4 times;
- a reversal of the trend towards a decrease in the share of machinery, equipment and vehicles in the export of goods and a steady annual increase in supplies;
- increasing the coefficient of export commodity diversification;
- growth of the share of services in exports by 1.7 times with an increase in the share of knowledge-intensive and intellectual services up to 20% (currently 14-15%);
- increase in the number of exporters by 3 times.

The main parameters of the target scenario for the development of the region's foreign economic activity by 2035:

- an increase in the value of exports of goods and services by 2.7-2.9 times;
- increase in the share of machinery, equipment and vehicles in the export of goods to 9-10%;
- increasing the coefficient of export commodity diversification by 1-2 points;
- doubling the region's share in world exports of high-tech goods;
- increasing the share of services in total exports by 1.8-1.9 times to 20%, with an increase in the share of science-intensive and intellectual services in the export structure up to 25%;
- 4 times increase in the number of exporters of goods.

The expected increase in the region's foreign trade turnover is presented in table 2.

Table 2. Growth rates of foreign trade turnover of the Chelyabinsk region per year, %

Development scenario name	2019-2020	2021-2025	2026-2035
Conservative	0,3	0,8	1,7
Basic	0,8	1,9	3,8
Target	1,3	3,1	5,2

Based on the foregoing, it is possible to predict the preservation of the export potential of metallurgical enterprises in the region, since most of them have modernized their production assets. Food producers are highly likely to increase their export potential. Higher dynamics is expected in the market of transport, tourism, telecommunications and computer services.

Abstract

The role of smart governance is currently increasing, with public participation as an important element. However, practices of participation in city management are still too limited and solutions are constantly being sought that can increase citizens' activity in the life of local communities. Showing various forms of public participation and its practical examples may influence the extension of the scope of existing activities towards participation in governance by local authorities and its residents. The aim of the article is to present the essence of public participation and to analyze the degree and areas of its application in leading Polish cities. In the theoretical part of the article, based on literature studies, a model of public participation in local self-governments was created, which was then used for the analysis carried out later in the discussion. Empirical research using the case study method was conducted on the basis of selected Polish cities, the most advanced in terms of implementing the idea of smart governance and thus the implementation of participatory practices. Research results indicate that participation has an impact on the development of local self-governments and is an increasingly important element of smart governance. Various participation tools are used, but some of them are not as important yet. In addition, the mere possibility of participation does not prejudge its effectiveness, as a large proportion of residents do not show interest in this area. ICT technologies are widely used to communicate with stakeholders, which may give the possibility of quick and effective consultations available to many social groups. The most popular tool for participation are the participatory budget and consultation, whose visible effects motivate city dwellers to use this form of participation in local management.

Keywords: Participation, Smart Governance, Smart City, Local Government, Public Management.

Introduction

Literature research as well as applied practices indicate that with the introduction of modern management concepts in the public sector, there is a need to change the approach to the existing relations between public administration and its stakeholders. The changes introduced were aimed at ensuring transparency of the activities of public entities, treating the existing petitioners as clients and introducing participatory actions. NICT - new information and communication technologies play an important role in achieving the adopted objectives of these changes (Nam, Pardo, 2011; Ruhlandt, 2018). Initially, they were the basic tool of the new method of administration functioning called e-government. It was mainly meant to improve the functioning of internal processes in the administration, to improve its efficiency, as well as to improve access to public information and increase the quality of public administration services. The introduction of this concept initiated further transformations towards smart governance, where public participation plays an important role and civil society becomes a policy maker (Michels, De Graff, 2010). The participation of the local community allows for a real recognition and consideration of the needs and expectations of the inhabitants in shaping their immediate environment in accordance with the sustainable development policy (Steinert et al, 2011; Meijer et al, 2016; Castelnovo et al, 2016). The aim of this article is to present a theoretical model of the public participation process in local government units and then to indicate its selected practical aspects on the example of the best developed smart cities in Poland. The first theoretical part of the article defines the place of the participation process in smart city management and then presents a model approach to this process. Then, on the basis of the indicated approach in the further, empirical part of the considerations, an analysis of activities indicating the main directions of development of participatory processes was made. The last part of the article presents conclusions from the research.

State of the Art

The Role of Smart Governance in City Management

Smart governance is especially important in city management (Tomor et al, 2019). Smart governance means that various groups of stakeholders can participate in making public decisions as well as use modern forms of public services. The use of New Information and Communication Technologies allows to tighten cooperation between citizens and city government (Alawadhi, Scholl, 2016; Pereira et al, 2018). Moreover it shapes new forms of relations, opportunities for dialogue and building consensus between citizens, institutions and organizations. Therefore, "intelligent co-management" does not mean the independent provision of services by public authorities, but creates space for the activity of citizens and entrepreneurs, entrusting a significant part of its tasks to private partners and non-governmental organizations. Public administration communicates and consults with residents both when establishing development priorities and when determining the goals of spending funds from the budget of a local government unit.

Thus, it can be stated that smart governance in relation to cities is a creative way of governing a city, in which the society, through the use of information, communication and technology integration, is involved in the process of planning, managing and implementing activities in various areas of city functioning in order to create sustainable public values, which is in accordance with the principle of sustainable development.

The characteristics of smart governance are:

- integration of undertaken activities (Chourabi et al, 2012),

- aiming at constant improvement of management quality,

- openness and transparency of activities (Baud et al 2015; Kim et al, 2005; Scholl &Scholl, 2014a),

- striving to improve the quality of public services provided, well-implemented e-government (Giffinger et al, 2007),

- social participation (Kim et al, 2005),

- the use of ICT (smart administration, the possibility of providing integrated services and using various electronic ways of communication (Odendaal, 2003; Picazo-Vela et al, 2012; Kavanaugh et al, 2012).

Smart government implementation must also prioritize digitization in any government action in favour of social services (Scholl &Scholl, 2014b; Bernardo, 2017).

Participation - definition and model approach

Public participation is a process of deliberation in which interested citizens, institutions and non-governmental organizations are involved in creating public policy before a political decision is made. (Council of Europe, 2019). In the participation process, the elements of entry are participants in the process, specific conditions of the participation process, including opportunities in the field of information and communication systems. However, the elements of the exit are conscious participation in the life of society, co-creation of public policy as well as its measurable effects. The model of the participation process is presented in Figure 1.

Figure 1: Model of the participation process.

Source: own study.

Stakeholders in the process of participation in local governments are their inhabitants, institutions, organizations, economic entities as well as the local administration itself. In order to undertake participatory activities, it is necessary to have access to information resources as well as other resources which are necessary in specific forms of participation, such as financial resources in participatory budgets. It is important that there are also adequate regulations with regard to opportunity of community participation in local policy making. Participation can be related to its various areas, both in terms of the thematic scope and the nature (or level) of participatory activities. The main thematic areas of citizen participation are:

- electoral participation - participation in elections and referenda, elections of local authorities, dismissal of the authorities, participation in the election campaign (Rallings et al, 1996; Frandsen, 2002).
- transparent information flows (Kim et al, 2005),
- vision, strategy and future of the local community and the city (Meschede, Mainka, 2020; Berry et al, 2019),
- spatial development (Kikosicka, 2014; Meilvang et al, 2018; Wójcicki, 2013),
- transport and communication (Niemeier et al, 2015; Kauf, 2018),
- ecology, environment (Kauf, 2018),
- safety (Ombler et al 2016; Alibegović, Slijepčević, 2018),
- local budget,
- social problems (e.g. poverty, unemployment, homelessness) (Kauf, 2018),
- culture,
- consultations on documents adopted by the local government,
- standards of public and social services (quality of administrative services, standards of senior care services) (Alibegović, Slijepčević, 2018),
- participation in the creation of civil dialogue units and other auxiliary units.

Participatory activities can take various forms depending on the area and level of participation, stakeholder group, the purpose of the participatory activities and the resources available.

The hierarchy of participatory actions according to the level of their advancement was presented by Arnstein (1969), who defined eight levels, from the least to the most advanced. Arnstein distinguished: manipulation, therapy, informing, consultation, placation, partnership, delegated power, and lastly citizen control. The first two levels do not allow for participation, and up to the fifth degree there is no certainty that a change will be made, as the final decision rests with the rulers. We can talk about proper participation from the stage of informing the inhabitants to co-governance.

Public participation used in city management also has disadvantages. The undesirable effects of participation are, for example:

- improperly planned or improperly conducted public consultations, which may have negative consequences such as the feeling of losing time or disregarding their participants.

- poorly organized participatory activities, which may discourage the local community, reduce trust in local authorities as well as in the entire democratic state system. They may also exacerbate existing disputes rather than lead to cooperation between residents.

- social participation may also lead to forcing one's own interests rather than the interests of sustainable development of local communities.

Moreover, according to the conducted research, more affluent and educated inhabitants, less educated and excluded from society, participate in civic activity. Thus, the projects support those social groups whose situation is relatively good. They often do not contribute to the reduction of poverty and social inequalities, and often lead to deepening differences. Social activity alone will not overcome the weaknesses of civil society, such as the lack of effective cooperation of the local community in achieving the set goals. Therefore, effective state control seems to be essential. Participation requires a strong state and civil society should develop in a strong symbiosis with the state and not next to it (Mansuri, Rao, 2013).

Field of Empirical Research

The paper was prepared using the method of critical analysis in the literature (Cottrell, 2017). This analysis made it possible to create a proposal for a model of public participation process of local government residents. Due to the scope of the issue, only some important aspects indicating the directions of changes in the participatory processes of the studied cities were examined. Two Polish cities were subjected to empirical research - Warsaw and Wrocław, which were included in the top 100 of the smart cities ranking around the world "IESE Cities in Motion Index 2020" and thus were recognized as the smartest cities in Poland (Berrone, Ricart, 2020). Warsaw was placed on 54th position, while Wrocław took 88th place. Warsaw is the capital and the largest city in Poland situated in its central part, it covers an area of about 517 km2 and is inhabited by over 1.79 million people. Wrocław, on the other hand, is the fourth largest city in Poland, located in the south-western part of the country. Its area is approximately 292 km2 and the number of inhabitants exceeds 642,000. Case studies were conducted on the basis of materials provided by city offices, as well as through the own observation of citizens' participation possibilities in the local politics of the examined cities.

Results

Possibilities of participation defined by local legal regulations

An extremely important issue in the topic of public participation is to define the foundations of its functioning and to define the directions of its development that enable interested parties to participate in such a process. Basic local legal regulations and documents relating to participatory activities are the city charter (Public Information Bulletin of City Hall of Warsaw 2019 , Public Information Bulletin of City Hall of Wrocław 2018)(, ordinances of city authorities, resolutions of the city council, including the city's strategy. They concern such issues as:

1. Possibility of a local referendum in resolving important matters.
2. Possibility of cooperation of the City with other local government units, as well as with other entities, including non-governmental organizations.
3. Transparency of activities of the City authorities:
- citizens' right to obtain information,
- access to sessions of the Council and meetings of its Committee,
- access to documents resulting from the performance of public tasks.
4. Elections to the City Council.
5. Social consultations in various areas.
6. Establishing advisory and consultative bodies in the form of youth councils and senior councils.
7. Rules and procedures for a group of persons having active electoral rights to take the initiative to adopt a resolution or position by the Council.

In addition to local legal acts, civic participation in cities is also regulated by national regulations on access to public information (BIP), the functioning of local government units, public finances and election law.

Communication and providing access to information

One of the basic elements of civic participation and a condition for its operation is to provide access to public information. This information can be made available on a voluntary basis and can be of a general, informative nature related to the life of the community, e.g. cultural events. Another type is obligatory information resulting from the statutory obligation to publish public information. This type of public information should meet certain requirements specified in the Act (The act of 6 September 2001). It includes e.g. information concerning the regulations in force, the structure of public administration bodies, the procedures in force, as well as contact details of individual units. The third type of public information is that which is made available at the request of a citizen. Dialogue and the nature of information influence the development of civic attitudes and the decisions made by the authorities (Krakowiak-Drzewiecka, 2015). Moreover, transparent information and good communication builds the trust necessary to undertake civic activity (Castells, 1983; Putnam, 1995, Fukuyama, 1997). Citizens should be able to use different forms of information and communication with the office, where modern information and communication technologies play an important role (Wieczorkowski, Paweloszek, 2018). The opportunities to engage in public life without leaving home and on an anonymous basis represent a significant qualitative change in the building of civil society today (Sobol, 2018).

The cities surveyed, which apply participatory practices, publish information in electronic form to a large extent. Their most advanced form is the publication of open data, i.e. data available to any interested party, which has been created by or on behalf of the authority. They are publicly available and ensure transparency of the local administration's operations, and are updated on an ongoing basis. They relate to many areas, the most popular are: urban transport, spatial data, local government budgets, education. According to the form of its availability, they have been divided into five categories, in order from the least to the most advanced ones in the pursuit of open connected data (Berners-Lee, 2006):

1. Providing data on the website in any format,
2. Data in a structured form, e.g. an Excel file instead of a table scan (xls),
3. Information available in a structured form with an open structure, e.g. (CSV) or XML,
4. The use of URI and RDF links to describe data,
5. Use of contextual URI links to other sources (open linked data).

The studies carried out show that information are made available in different forms depending on the type. Information on public transport deserves special mention, where it is updated on an ongoing basis and is available in various formats, also via a mobile application. The introduction of open data is a relatively new concept introduced in the last few years and still being developed in the cities surveyed. The characteristics of the area and forms of open data provided by the surveyed cities and the main modern forms of communication are presented in the table 1.

Table 1: The area and forms of open data provided by the surveyed cities and the main modern forms of communication

	Warsaw	**Wroclaw**
open data areas	Culture Urban transport Education Ecology Properties Spatial data Security Official data	Transport Spatial data Town Hall Education Sport and recreation Weather data Events Other
Format of the shared data	JSON, CSV	CSV, XLS, SHP, HTML, XLSX, WMS, ZIP, WFS, DOC, CSW
Modern forms of communication	Online chat Instagram Facebook The City Hall's website Warsaw Portal Warsaw 19115 - Municipal Contact Centre for residents (24 h/7 days a week) Mobile application Warsaw Notification System	Online chat Instagram Facebook The official website of Wrocław Residents' notification system

Source: own study.

In the largest city in Poland, the format of shared data is unified and it can be determined that according to the Berners-Lee model it is in the third phase of data sharing. The scope of available data is quite large and its extension is planned.

An example of good practice in the city of Warsaw is the use of modern forms of communication with its residents, including the portal Warszawa 19115, dedicated to the residents, which enables 24-hour contact in such matters as:

- obtaining full information on services provided by the City Hall and municipal units (information),
- reporting a problem that should be dealt with by municipal services (intervention, e.g. damaged traffic lights),
- to give your own idea of how to improve the city (initiative/free application),
- possibility of constant monitoring of the implementation of the reported case (report status).

In addition, it is also available in a mobile version as an application. Based on this solution, the Warsaw Notification System was created, i.e. a free information system. It is supposed to simplify their everyday life in the capital city. It provides information from various areas of city life on an ongoing basis. An inhabitant can choose the categories and locations they are interested in - districts to be notified about. The system will also automatically send messages about local threats.

Consultations

Another level of advancement of citizens' participatory activities is a form of public consultation, usually initiated by the city authorities. A characteristic feature of consultations is a two-way information flow, which can occur at any stage of management, from the identification of the problem to the assessment of the changes introduced. It can be a one-stage process or, as is increasingly common, a continuous dialogue (OECD, 2020). Among the activities related to it, we can distinguish consultation meetings, public forums, public hearings, public opinion polling, meetings with the city mayor and a citizens' panel. Public consultations should meet the following principles (Ombler et al, 2016):

- those affected by the decision of local authorities should have adequate access to information and be encouraged to express their views,

- residents should be clearly informed of the purpose of the consultation and the scope of the decisions to be taken,

- should be given an adequate opportunity to present their opinions,

- local authorities should be open to innovative ideas,

- participants should have access to reports related to the implementation of decisions taken jointly.

Citizens' panel

The Citizen's panel is a relatively new solution and has only just been introduced in the examined cities. At the local level, a group of inhabitants is randomly selected to participate in the Citizens' panel, taking into account demographic criteria such as gender or age. This group constitutes a "city in a nutshell". The role of the citizens' panel is to analyse a specific subject in detail, discuss various solutions, listen to the arguments for and against, and then make conscious and thoughtful decisions. In Wrocław, a civic panel was established on the problem of improvements in the movement around Wrocław, including the improvement of quality of life and climate protection (Ordinance of the mayor of the City of Wrocław, 2020). In Warsaw, on the initiative of young people, a civic climate panelis to be created (Ordinance of the mayor of the City of Warsaw, 2020). In Wrocław, the citizens' panel is composed of 75 people drawn, with an additional 10 taking part as participants and reserve participants. According to the declaration of the President of the City of Wrocław, the recommendations which will be supported by at least 80 percent of the panel will be treated by him as binding, i.e. will be indicated for implementation. The rules of functioning of the citizens' panel are specified in the regulations. They contain a description of the panel's standards, its thematic scope, the panel's schedule, definition of the coordinating and monitoring team, the method of appointing panelists and the rules of its functioning (Rules of the first Wrocław citizens' panel).

Public Consultations

Public consultations are a popular form of citizens' participation in creating the policy of local communities of the examined cities. It is a formal, phased process that follows the methodology and aims to provide reliable information to agree on a project, plan or strategy. Public consultations take place in accordance with a specific methodology and are mainly aimed at presenting doubts, questions and proposals of stakeholders on matters which they can directly influence. Social consultations generally address similar issues such as environmental protection, land use, social problems, public transport problems and culture. The table 2 shows the areas of social consultations conducted in Wrocław and Warsaw.

Table 2: The areas of social consultations conducted in Wrocław and Warsaw.

	Warsaw	Wroclaw
Public consultation areas	Digital transformation of the city Electromobility Zoning plan Solving social problems Environmental Protection Municipal greenery Urban transport Culture Parking of vehicles Development of tourism in the city of Warsaw Climate change Changes in the statutes of city districts Organization of city events Establishment of a secondary school Settlement matters	Consultation of the civic budget City revitalization Ecology Parking of vehicles Improving participatory processes City transport Municipal greenery Culture Spatial development Wrocław's strategy Social policy strategy Settlement matters Create streets, street names Climate change Recreation and playgrounds for children Electromobility
Number of completed consultations from 2016 to 07.2020	271	53

Source: own study.

All consultations conducted can be divided into obligatory and non-obligatory. Those of an obligatory nature may include, for example, consultations on changing the boundaries of city districts, spatial development, creation and abolition of auxiliary units, development projects or consultations on additional names in the minority language (The act 1990, The act 2003a, The act 2003b, The act 2004, The act 2005, The act 2006). The need for such consultations results from national legislation. Noteworthy are the consultations on climate change and its prevention, as well as electromobility. In addition, the cities surveyed conducted consultations, which aimed to develop practices that increase the participation of residents in participatory processes.

In order for the consultations to be effective it is necessary to maintain appropriate rules such as: listening to each other and trying to understand different arguments, universal and transparent consultations, responsiveness, coordination, creating clear rules and defining the planned course of consultations, respect for the general interest (OECD, 2001). The efficiency of the course of public consultations should be ensured by the regulations created for these purposes.

It is particularly important that information about planned consultations is generally available to interested parties. An important role is played here by the information portals of cities, as they clearly present information on consultations that have been conducted and completed so far, as well as those that are ongoing or planned.

Codecision

Codecision is the highest level of public participation, where the initiators of change are the citizens themselves, who participate in all stages of the decision-making process related to public policy-making. The most advanced forms of public participation include: legislative initiatives and active participation in the preparation of the legislative process, participatory budget and local initiatives.

Since 2018, in Polish law, there has been a possibility for residents of local government units to submit a civic initiative to decision-making bodies. It enables a group of people to submit a draft act of a local law, which will be considered during the City Council. A local initiative may concern the entire city or each of its districts. The group must have the right to vote and live in the same district or city and its number depends on the number of people living in a given local government unit. This solution has been used many times in the largest city in Poland. In Wrocław, on the other hand, since 2019, three such initiatives have been undertaken, two of which concerned recycling.

Another form of participation in the examined cities is a local initiative. According to the adopted rules in Warsaw, it has to be represented by at least two people or a non-governmental organization. To ensure the efficiency of this form of public participation, coordinators were appointed in each district. The submitted projects should relate to activities supporting the development of local and charitable communities; activities for the benefit of culture, art, protection of cultural assets and national heritage; revitalization; promotion and organization of volunteer work; education and upbringing; activities in the sphere of physical culture; tourism or nature protection. Residents engage in the implementation of the local initiative primarily in the form of social work, but also material and financial contributions. Within the framework of the local initiative, the municipal office does not transfer money directly, but may pay for the purchase of materials specified in the project or the commissioned work. In Wrocław, a program to support local grassroots initiatives was also defined and divided into three types: microgrants for individuals and informal groups, microgrants for non-governmental organizations and microgrants for informal groups of young people.

Participatory Budget

Another advanced participation tool is the participatory budget, which enables citizens to actually co-decide on how to spend part of the local budget (Rachwał, 2013). It encourages residents to look at the mechanisms of constructing and spending local budgets, and forces them to make decisions on spending priorities, as well as to consider the vision of the development of a given locality. A participatory budget must follow certain rules, such as (Sintomer et al, 2008; Sintomer et al 2012):

- transfer of a certain amount from local government funds to the participatory budget,

- the opportunity for every citizen to participate ,

- the need to hold public meetings and debates,

- implementation of projects selected by citizens' vote,

- reporting on budget implementation,

- it has to be a long-term action, not a one-off.

In the examined cities this tool has been used for several years - in Wrocław since 2013 and in Warsaw since 2015. Figures 2-3 show the number of positively assessed project proposals allowed to vote, as well as those selected by citizens for implementation in Warsaw and Wrocław in 2015-2019 .

Figure 2: The number of positively assessed project proposals allowed to vote, as well as those selected by citizens for implementation in Warsaw in 2015-2019. Source: own study.

In Warsaw, the number of projects underway shows an increasing trend (Reports on the evaluation of warsaw's participating budget in 2015-2019). Inhabitants show great initiative by presenting as many as 5,000 projects in the

last three years, which were allowed to vote. Out of these, 48% have been implemented, which indicates that there is great potential for influencing local initiatives within the framework of the civic budget.

Figure 3: The number of positively assessed project proposals allowed to vote, as well as those selected by citizens for implementation in Wrocław in 2015-2019.

Source: own study.

The number of projects implemented in Wrocław is systematically falling (Reports on the evaluation of wrocław's participating budget in 2015-2019). However, this does not result from the reduction of funds allocated to the annual civic budgets. Fewer projects are being implemented, but they are more cost-intensive and require more money. In 2017, an additional edition of the citizens' budget took place in Wrocław, the purpose of which was to invest in urban greenery. An additional 8 projects were implemented. So in 2017, 72 projects were completed.

The scale of participation in the civic budget can also be proved by the number of people who expressed their opinion by voting for selected projects. The number of persons voting in the surveyed cities is presented in Figure 4.

Figure 4: The number of people voting in the surveyed cities.

Source: own study.

As the two cities differ significantly in terms of the number of inhabitants, Figure 5 shows the percentage of inhabitants who took part in the vote on the civic budget in both cities.

Figure 5: The percentage of inhabitants who took part in the vote on the civic budget.

Source: own study.

It can be seen that in the smaller city (Wrocław) relatively more people are interested in the civic budget. At the same time, a decreasing trend can be indicated in relation to the number of people interested in this form of participation in both cities. This phenomenon is also observed in other cities.

Participatory budgeting can be implemented on a city scale, but also in smaller units. An example of such a budget is the first civic budget of a community centre in Poland. The residents worked out programme proposals for the activities of the community centre using the form of individual interviews, workshops and working groups. Then these proposals were implemented.

Discussion and Conclusions

In order to develop the process of participation, it is necessary to ensure its proper foundations, such as good quality public information and various forms of communication, appropriate regulations enabling the inhabitants to influence the city's activities, appropriate well-designed participation tools and the willingness of the local community to get involved. Civic participation is essential for the directions of city development. A wide response from citizens requires the use of many different participation tools and encouragement to use them.

So far, the main forms of co-decision in the examined cities have been social consultations and citizen budgets. In recent years, there has been a development of local initiatives, including the resolution initiatives that have been possible for two years. Adequate access to information on the possibilities of participatory activities, along with instructions on how to proceed and the possibility of direct contact, makes it easier for residents to participate in the life of the local community. ICT plays an important role in providing access to information. The best solution in this case are dedicated internet portals such as Warsaw 19115. It is important to provide an appropriate, user-friendly interface and simple website navigation. The possibility of using such portals requires access to the Internet. It is also necessary to use various media to disseminate information and communicate with the inhabitants. such as social media. A good solution introduced in the surveyed cities was also to consult with the inhabitants on the possibilities of increasing their participation in local policy-making. Another measure introduced by the surveyed cities was the creation of advisory bodies such as the Youth City Council or the City Senior Council. It is also a good practice to create organisational units within the administration itself, designed specifically for the purpose of undertaking dialogue with the public. Participatory activities in cities can also be supported centrally by the state. An example is the Human Smart Cities programme run by the Ministry of Investment and Development. This programme assumes support for projects selected in a competition submitted by small, medium and large cities. Under this programme, 8 small towns, 15 medium-sized and 2 large cities were supported in 2019.

The basis for participation in smart cities is the residents' trust in the city authorities, as well as the awareness of the benefits that result from hearing residents by the authorities. However, it is not easy to achieve and requires long-term work and, above all, consistency in action. The lack of willingness to involve the residents in the development policy of the local community, and merely informing them about various types of projects, often leads to objections from the residents. Sometimes it also happens that the planned actions of the city authorities are consulted with the inhabitants, but their opinion is not taken into account (Laurian, Shaw, 2009). As a result, residents do not feel co-decision makers and do not consciously get involved in the city's affairs (Rowe, Frewer, 2000).

Abstract

The paper explores the development of technology platforms to ensure smart, sustainable and inclusive economy. Technology platforms are considered as the basis for elaboration of the common vision of scientific and technological development based on government-industry-science collaboration. Technology platforms are core element of innovative infrastructure and a way of implementing public-private partnerships. Technology platforms development requires identifying and selecting key sectors or areas of the future economy. The potential for technology platforms development on the country level should be based on special analytical technics including foresight technics and methods, considering the country's position and progress in STI development and existing opportunities for international collaboration.
Comprehensive multivariate analysis can be also applied for identification of new trends and opportunities for high-tech industrial development. Important attributes of progress are new high-tech services, start-ups in breakthrough technological areas where there are competitive advantages.

Keywords: Technology platforms, identification of promising technology areas, industry-science collaboration

Introduction

Technology platforms development is a methodological and resource basis to link government, business, science and education to implement a common vision of scientific and technological development and common approaches to the development of appropriate technologies. Technological platforms allow mobilize efforts, competences and resources of all stakeholders for the development of innovative technologies in certain strategic areas. Technology platforms are the core element of innovative infrastructure that is based on a mechanism of public-private partnerships.

Among the prerequisites for the efficient development of technology platforms, the authors highlighted: strategic technological challenges; the necessity of improving collaboration between core actors of innovation ecosystem; low efficiency and poor coordination of state support instruments for R&D and innovation development; fragmentation of scientific activities and low level of science – industry collaboration.

Digital economy requires implementation of digital solutions for technology platforms development. Stimulating demand for innovation and increasing the efficiency of commercialization processes, introducing innovative ideas into the real sector of the economy is significant for innovative economy development.

In Kazakhstan technology platforms are viewed as a methodological basis for connecting representatives of the government, business, science and education to implement a shared vision of scientific and technological development and common approaches for advanced technological development. Technology platforms allow mobilize efforts, competences and resources of all stakeholders to develop innovative technologies in certain strategic areas.

Countries with developed science and technology are using technology platforms (hereinafter - TP) as a tool for the developing a competitive and high-tech economy. According to the internationally accepted definition of TP are objects of innovative infrastructure that allow effective communication and development of advanced technologies,

SHEVCHENKO " Technology Platforms as a Core Element of Innovation Infrastructure and a Model of Interaction Between Government, Industry, Science and Education" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

high-tech, innovative and competitive products based on the participation of all actors (government, industry, science, education, public organizations). In the EU, technology platforms are a demand-driven innovation policy tool (Rudnik, 2011)

One of the problems hindering the technological development of Kazakhstan is a low level of collaboration between government, industry, research and education, which lowering technological and innovative development. The process of identification of key areas for the development of technology platforms, as well as the further implementation of TPs requires appropriate methodological support. In this regard, it is necessary to develop a methodology for evaluation and selecting priority areas for the National TPs development.

TPs are considered as:

1) an object of innovation infrastructure;
2) a way to mobilize efforts and resources of all interested parties - various ministries and agencies, business, scientific community to create innovative technologies in certain strategic areas;
3) a mechanism for coordination activities of all stakeholders, involved in the process of the national scientific and technological policy implementation;
4) the way to develop public-private partnership.

At the same time multisectoral development of TPs has critical importance for the development of network structures that represent a characteristic feature of the new economy (Akberdina, Smirnova, 2018).

In this regard authors focus on theoretical and methodological foundations of the formation of technological platforms as a tool for integration of interests of all groups of stakeholders (government, industry, science and education) on the implementation of common vision and strategy for technological development.

The main feature of TPs is that they are developing in the areas with high technical complexity and high export orientation.

An important issue that needs to be resolved within the framework of this work is the development of a methodology for assessing the prospects and selection of priority areas for the development of technological platforms.

EU, Russia, Great Britain, Singapore are designing of TPs as a complex instrument of science, technology and innovation policy (further – STI) implementation that require a strong methodological support at the stages of TPs designing and implementation.

At the same time, many researchers believe that TPs could be developed based on the positive experience of the EU countries. Zlyvko O.V. and Lisitsyn E.M. (Zlyvko, Lisitsyn, 2012) based on the experience of Russia in the implementation of TPs highlighted importance of methodological support for TPs development.

Foresight on the national level (foresight research) is a multi-stage interactive process that includes a set of various methods, such as expert methods, economic and mathematical forecasting models (trend extrapolation, econometric modeling). However, mathematical forecasting methods have a rather significant limitation for application in complex systems - they are most effective for systems with a stable development trend, not for the situations of high volatility and uncertainty.

In turbulent times, the pace of change accelerates, global competition intensifies in many sectors and new players come to force. To avoid the disorientation associated with the pace of economic globalization, governments should concentrate on the long-term development of the most important sectors of the national economy (International Labor Office, 2014).

An important advantage of econometric modeling is the ability to consider the influence of external economic factors. Econometric models allow solving a wide range of research tasks: analysis of cause-and-effect relationships between economic variables; forecasting the values of economic variables; scenarios elaboration based on simulation experiments with the model. Modeling and forecasting macroeconomic processes are undoubtedly an urgent problem of the economy.

However, among the weaknesses of econometric modeling is that the method requires comprehensive databases (statistical, economic, sectoral data, etc.) and is more suitable for extrapolating existing trends than for recognizing weak signals of change.

The objective of the paper is to explore methodological approaches to the development of TPs, based on the STI development priorities.

The scientific novelty and significance of the paper consists of the development of a approaches for TPs designing and implementation based on a combination of several advanced techniques that make it possible to implement the basic criteria for assessing and selecting priority areas, including the use of foresight in combination with multifactorial analysis and mathematical modeling.

Materials and Methods

Among the methods for identification of priority sectors for TPs development that can significantly influence the development of the whole industry, can be mentioned such methods as patent and bibliometric analysis, analysis of "weak signals", horizon scanning, etc. The above methods allow early detection of technological trends in the development of groups of technologies within certain areas that have the potential for explosive development in the future. These methods should be considered in developing methodology for assessing priorities for TPs development. To collect the data different data sources should be used, such as statistical databases, results of foresight exercises, analytical reviews, etc. It is important to combine datasets from different data sources to increase objectivity and credibility.

Development of a methodology for identification of priorities for the development of TPs on the national level should be based on a set of tools and techniques described below.

Basic methods of foresight can be applied on the stage of identification priority areas and key sectors for TPs development, such as horizon scanning, emerging trends analysis, weak signals, wild card, STEEPV, BMO analysis, etc. In order to effectively anticipate or scan possible futures, it is important to clearly understand key parameters and basic elements to define future priorities in situations of uncertainty and volatility.

Horizon scanning allows capturing weak signals as an indicator of a potentially emerging issue, that may become significant in the future. Such approaches as traditional planning based on trends extrapolation can be successfully used under relatively stable external conditions. However, given the acceleration of historical time, these techniques lose their effectiveness and can provide misleading results. The same time horizon scanning allows to identify possible threats or emerging opportunities at an early stage and to use this information as a competitive advantage.
In identifying global technological trends, the patent analysis plays a significant role in exploring new trends and emerging market niches.

Foresight plays an important role at the stage TPs designing by providing instruments for priority areas identification. Foresight provides mechanisms for mobilizing all stakeholders on the initial stage of TPs development. On this stage a common strategic vision is formed with further gradual detailing by involving expert groups, conducting in-depth interviews, developing roadmaps and identifying multisectoral intersections, in order to identify tasks that can be most effectively solved by combining efforts, resources and technologies of all actors to ensure synergistic effect.

Foresight results will provide understanding which areas (sectors) will have a leading position on a global scale and which countries can be at the forefront of their development and what competencies should be developed to ensure a qualitative breakthrough in the selected priority sectors of the future.

Results

TPs can be formed on a basis of foresight results, considering the importance of the economic sector in terms of implementing the priorities of the country's socio-economic development, for solving such problems as:

1) Linking needs of business and society for implementation of the most important areas of scientific and technological development;
2) Identification of new scientific and technological achievements for the modernization of existing sectors and the formation of new sectors of the economy;
3) Determination of the principal directions for improving industry regulation for the rapid spread of promising technologies;
4) Stimulation of innovation, support of scientific and technical activities and processes of modernization of enterprises, considering the specifics and prospects for the development of industries and sectors of the economy;
5) Expansion of scientific and industrial collaboration and the formation of public-partnerships in the innovation sphere;
6) Improvement of legal regulation in the field of scientific, scientific-technical and innovative development.

In EU countries TPs are considered as a tool for cooperation and coordination of the implementation of innovation policy, increasing openness and interaction of all participants to achieve a common goal. In this regard TP are viewed as a tool for increasing industry-science collaboration (Zhogova, 2019).

Discussion

In the process of priority sectors identification for the development of TPs fulfillment of the following conditions is important: 1) the formation of platforms should be based on implementation of digital technologies, 2) scalability from the standpoint of economic effect and 3) the development of an innovative component, the development of multisectoral cooperation and obtaining a synergistic effect.

In the context of a new technological paradigm and the transition to a digital industry that caused transformation in production, sales, logistic chains, natural resources are no longer a competitive advantage and country's competitiveness is increasingly dependent on the introduction of science-intensive technologies, formation of creative economy and development of advanced competencies. Currently we can observe trend of arising technologies of the Industry 5.0 that focus on the interaction between humans and machines. This trend is developing in parallel with the Industry 4.0 (Golov, Mylnik, Palamarchuk, 2018). Society is moving to a new stage of reindustrialization, the development of production in a qualitatively new environment based on networking technologies. In this direction, the development of technological platforms is seen as a promising tool for ensuring sustainable development based on the principles of openness, involvement, collaboration and a wide application of the achievements of digitalization and project management.

In the EU countries development of TPs was carried out using complex schemes for supporting scientific and technological sphere, using the possibilities of such large research funding programs as "Horizon 2020". It aims to improve conditions and access to finance for research and innovation in Europe, to ensure that innovative ideas can be turned into products and services that create growth and jobs. TPs aims to involve all actors and all regions in the innovation cycle by revolutionizing the way of public and private sectors collaboration.

However, in the circumstances of Kazakhstan, elements innovation ecosystem as well as instruments of state support of science, technology and innovation development require more efficient inter-ministerial coordination. In this regard targeted long-term mechanisms to support the country's innovative development should be implemented on the national level, including implementation of technology platforms.

In the Russian Federation, the implementation of TPs is aimed at bridging the gap between science and business, as well as forcing big national companies with state participation to increase R&D collaboration and to implement advanced technologies into production process through participation in TPs. TPs should help to introduce long-term interaction mechanisms and consolidated STI policy of all participants in relation to the prospects for scientific and technological development, forming (Protocol of the State Commission of the Russian Federation, 2010).

Analyzing the experience of Russia and the EU countries in the development of technological platforms, we can conclude that the basis of their formation lies in solving the strategic tasks of scientific, technological and innovative development, and they are considered as one of the mechanisms for the effective promotion of priority scientific and technological areas identified within the framework of long-term scientific and technological forecast using the foresight method.

Conclusion

1. Among the main methods for priority areas identification that can have a decisive influence on the development of the industry, should be highlighted such methods as patent and bibliometric analysis, weak signals, horizon scanning, etc. These methods allow early detection of emerging technological trends within certain areas that have the potential for explosive development in the future. The assessment of national technology platforms should be carried out on a competitive basis within the framework of national priorities identified based on technology foresight methods.

2. In the process of selection priority areas for technology platforms development, it is necessary to identify key technologies based on attractiveness and feasibility criteria. Identification of priority areas of TPs development will allow concentration of limited resources on strategic fields and key technologies (Shevchenko, Stukach, 2019).

3. It is advisable to analyze the multiplicative effect on the development of related sectors and fields. In addition, internal competency level that include technological readiness, technology life cycle, the country's position in STI development in comparison to the leading countries, as well as potential for international collaboration should be

evaluated. This comprehensive multivariate analysis will become the basis for determining strategies for high-tech industrial development, as well as the development of startups in promising technological fields in which the country has competitive advantages.
4. The following main stages for TPs priority areas identification are proposed:
- assessment of strategic prospects based on the selection and analysis of complex full cycle projects;
- analysis of value-chains inside TPs based on intersectoral approach;
- identification of the prospects for the development of the scientific and innovative component by linking needs of business with competences of research.
- assessment of the needs for digitalization of the technology platforms to enhance the overall effect of TPs development. 4. Technology platforms facilitating performance of the priority sectors based on a network structure that supports an innovation activity of all actors of the national innovation ecosystem. At the same time, in the digital economy, digital platforms provide solutions that become a basis for the formation of business ecosystems with high level of communication among all stakeholders and accumulation of limited resources for production of technologically advanced products and services (Boyev, Ponomaryeva, Haibullin 2019).

Abstract

Value at risk (VaR) is an attempt to represent by a single number the total risk in a portfolio of financial assets. This measure was introduced by J. P. Morgan in 1994 and is now widely used by both financial institutions and corporate treasuries and investment funds. The Banking Supervisory Committee of the Bank for International Settlements also uses it to calculate capital requirements for banks. The advantages that risk-value estimation offers lie in its ability to express quantitatively, numerically, the level of risk of a portfolio at a given time as well as that of a certain open position (in capital market securities, loans granted , investments in currencies, etc.) by an economic agent, in this case a financial-banking institution. In this research, the VaR was calculated for a portfolio of currencies held by a bank in order for an investor to be able to find out what is the maximum loss expected from this investment. Considering the unpredictable changes coming from the external environment, we consider that it is important for any financial or investment actor, to be able to predict the maximum loss expected after an investment.

Keywords: Value at Risk, financial markets, investment decision-making, behavioral economics.

Introduction

The environment is constantly changing and the effects it can have on all activities undertaken by investment or financial actors. Among the economic systems that have aroused a special interest to specialists in the field of complexity sciences, the financial market occupies a privileged place. The classical theory of the financial market, developed on the basis of Alfred Marshal's conception of the formation of market equilibria, starts from the idea that a probabilistic connection between cause and effect can be determined and that this connection is predictable. When a financial market is subjected to an exogenous shock, such as, for example, the news regarding the evolution of the economy, the market can absorb this shock and return, after a finite time, to a new state of equilibrium. Although many of the theories that inspired this mechanistic conception have changed in the meantime, such as the emergence of Heisenberg's indeterminate principle, which today underlies quantum physics, in economics this progress has not occurred so quickly. Many of the conceptions that dominate financial market theory today have their origins in scientific ideas and methods based on determinism and the predictability of cause-and-effect relationships.

In recent years, conceptions of financial markets have developed on the same basis, so that today they are still dependent on questionable or even erroneous assumptions, such as market efficiency and investor rationality.

One possibility to avoid false assumptions is to consider the financial market as a complex adaptive system. Financial markets, in particular capital markets, can be considered complex adaptive systems, they are composed of a lot of interdependent and connected agents, which show emerging group behaviors, acquired as a result of the aggregation of their individual behaviors.

Cite this Article as: Ionuț Costinel NICA, Nora CHIRIȚĂ, Andrei VIȘAN and Ștefan-Andrei IONESCU "Applying VaR on a Bank's Currency Portfolio in The Context of Increased Volatility of Financial Markets" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Agents in a complex adaptive system collect information from the environment, combine it with their own interactions with the environment, and hence their own decisions and decision-making procedures. Of course, these decisions and procedures will compete with each other, being compared to a fitness and only the most effective decision strategies will survive. This makes the system adapt to changes in the environment over time and respond appropriately to anomalies.

The VaR methodology represents an area that all these actors must know and understand, considering the unpredictability and sensitivity created by the uncertainty of the evolution of external factors. This research presented how a variation of the VaR methodology can be applied to estimate the maximum potential loss if an investment decision is to be made. Moreover, it can contribute to the choice to make the investment or not.

The data used in the article are real, taken from the public database from the National Bank of Romania and refer to the exchange rates. The calculation method can be extended to a much wider period.

An important lesson from the 2007-2008 financial crisis is that banking regulation should be based on macro-prudential rather than individual financial institutions. The financial distress has spread at a disastrous pace from the banking system to the real economy and has affected global financial stability.

Most banks use the internal model approach, due to the efficient and appropriate analyzes they offer. These models are based on variations of the VaR methodology and are performed using econometric models. In the first place, in terms of the degree of use in banks, the VaR methodology presents an efficient quantification of banking risk according to the fluctuations of the financial markets.

Literature review

Historically, the method of Value at risk has emerged since 1994 with the decision of Dennis Weatherstone, president of J.P. Morgan., To prescribe to employees the need to make a daily report on bank risk, to which to attach an appropriate risk measure. In this way, the RiskMetrics department was set up at the internal level of the investment bank, meant to analyze, estimate and evaluate the banking risk. (Phelan, 1997)

This activity gained momentum and led to the establishment of a methodology that was later spread under the title of Value-at-Risk (VaR). (Jorion P., 1996)

Currently this methodology is applied by economic agents and financial institutions, on top of that even by some non-financial ones. The pioneers of this measure, VaR, are Jorion (1997), followed by Dowd (1998), and finally Saunders (1999).

This paper is structured on the following sections: methodology, results and discussion and conclusions. The following chapter describes one of the statistical methods for calculating VaR. In the discussion and results section, we present step by step, in a way applied on a currency portfolio, how to calculate VaR. From the definition of VaR it is observed the fact that it specifies only a property that var should have, but it doesn't indicate a punctual way to calculate it. For this reason, the definition has a wide set of interpretations, which determined the separation of 2 different types of VaR, one of them regarding risk management and another regarding risk measurement.

From the point of view of a risk manager, VaR it is not just a number but a system rather. The system runs at a certain set period (usually one day) and the resulting number to be published is compared with the calculated price fluctuation in the opening positions over the time horizon.

To achieve success on the stock market, there is a set of features that an investor must acquire such as understanding the internal mechanisms, the ability to anticipate the meaning of a trend, but also keeping temperance to the influence of emotions in trading.

Another very important topic to analyze in the case of the investment decision-making process is the economic behavior of investors. Depending on this, they may decide to invest in a certain currency position, or not, in a more risky or less risky action. Although most economic theories consider that all investors are rational and that they base their investments on the use of all sources of information in the market, studies over time have shown that an individual investor most often enjoys small gains over long periods of time. Despite the fact that investment experience, specialized studies and the size of the capital involved are basic aspects characteristic of a successful player, the psychological factor that is often ignored proves to be very important, especially in situations where it is necessary to take setback decisions. So, there are a number of relevant psychological factors that need to be considered because they can affect success in the investment market:

- herd effect;
- overestimation of own investment skills;
- fear of investing larger amounts;
- market preconceptions.

The herd effect can be described as the lack of an own investment plan, and the decision to copy the behavior of close investors out of the desire not to miss the chance of a good transaction. The investor takes over the thinking of other investors so that he does not gain any experience but can also create imbalances in the market, because the massive increase in sales of a stock without having previously researched considerations can lead to a decrease in value. the whole market is losing ground, this phenomenon being based on a simple economic principle by which the increase of supply will gradually lead to the loss of value. The reason for the herd effect is the alignment with the group's trend, investors preferring the security of belonging to a group to the risk of owning. This reasoning is based on the hypothesis that the majority cannot be wrong, even if sometimes objective decisions are made that are irrational. The herd effect is the behavior specific to individuals who are new to the market and therefore do not have the necessary experience to make decisions based on their own ideas.

On the other hand, we can say that in small cases the adoption of this strategy may prove to be the path to success but we must mention two aspects that differentiate between success and failure, namely: maintaining long-term trust and motivation because profit does not come most cases quickly or in the way it was predicted. Such a herd investor will invest in a security that is currently profitable, but if the rate of increase in its value decreases over time and he observes new investment trends in other economic goods that are more profitable, he will reorient himself to those who fail to enjoy the fruits of his first investment. The second aspect to be analyzed is choosing the right time to invest, which is very difficult in practice, because once a trend becomes known by most investors, it becomes a trap, because new players will start investing after that economic good has already reached the peak of capitalization so that it will enter a downward trend that will affect the capitals of those who invested their money late. The best example of the deficiency of this psychological factor was the dotcom bubble.

Overestimation of own investment skills. This psychological aspect is very common for investors to make them more confident that their decisions will perfectly anticipate changes in the financial market, tending to establish models based on historical evolution, ignoring the reasons that led to that development and the chances of recurrence. just. The causes of this behavior are a wrong self-assessment, often investors after making a profit learn an overconfidence that does not really correlate with their skill level and looking for evidence to confirm the hypothesis that other players act instinctively while their actions are taken based on thorough research and rational thinking. Other mistakes that come with this psychological factor are: niche on a single type of assets that are considered to be well documented and easier to predict and the purchase of risky shares in order to obtain high profits.

Fear of investing larger amounts and greed: An unwritten law of investment success is to raise awareness and limit the influence of emotions in making investment plans. Successful investors when preparing for an investment know how to balance both pros and cons, overcoming the natural tendency to be fearful or greedy. This psychological factor can cause investors problems more quickly in situations where the market is declining and they choose to sell for fear of limiting losses, than if the market is growing slowly, being satisfied with lower gains. A very good example of the greed of investors is the "Internet Boom" of the last decade of the last century, when the shares of Internet companies peaked due to the greed of stock market players who wanted to get rich overnight, but in the long run, it was not possible to sustain the gains. Fear can also act in this way, many investors wanting not to lose capital by investing in stable securities that have a low risk but also a low return.

Market preconceptions. Prejudices are a human tendency that manifests itself by creating preconceived ideas about a hypothesis that are based only on instinct and not on concrete facts. The most common types of bias among investors are: confirmation bias, cognitive dissonance, familiarity bias, and stock-based bias.

- The prejudice of confirmation is a behavior by which a person who is about to make a wrong investment decision based only on their own opinions will analyze only those sources of information that further strengthen their drive to make this decision, not contrary ideas, thus creating a distorted image of reality, being very difficult to change. For example, an investor who is unsure of a company's bankruptcy will look for information only in those rumors that match his opinion.

- Cognitive dissonance is a state of discomfort felt when the person does not fully agree with the decisions made, in his mind there are simultaneously contradictory ideas. Underlying this type of behavior is the fear of regret in the future. Out of a desire to reduce the risk of regrets, shareholders will be reluctant to sell them, as their price could later rise. It was discovered after research that after the completion of an investment transaction, investors tend to critically overestimate the decision, which is assigned a higher degree of performance retrospectively than at the time of taking it to avoid regret. These actions are consequences of cognitive dissonance in the capital market.

- The prejudice based on familiarity represents the affinity of investors for shares in a certain sphere that is familiar to them. They are prejudiced towards their domestic markets, being optimistic about their evolution, while they have pessimistic expectations towards other markets, being indifferent to the opportunities they could offer.

- Retrospective bias is a characteristic of investors that manifests itself in a tendency to base their investment plan on past events, thus simplifying the analysis and acceptance of additional risks because it does not analyze the causes that influenced the trend to a certain point.

Methodology

Value at risk is the methodology used to estimate the market risk to which a bank is exposed and also to determine the minimum capital required for banks to cover this risk. (Jorion P., 2001) This measures the maximum potential damage that is possible to occur in a portfolio, in a certain period and related to a confidence interval.

Value at risk is the latest step in the evolution of risk management tools, combining the relationship between price and performance with the likelihood of unexpected market movements.

It takes into account the correlations between the portfolio's financial assets and the benefit effect, having a dual role, both in measuring market risk on an integrated basis and in determining the minimum capital required to cover banks' market risk.

The standard capital market risk, according to the Basel Committee, should provide for the daily calculation of VaR on a daily basis and the capital requirements related to market risk must be met on a daily basis.

Capital requirements are expressed as the maximum value of the previous day's VaR value and as an average of the daily VaR indicators for the last 60 working days. It is then multiplied by an additional multiplier k (whose minimum value is 3) designated by the national supervisory authorities according to the quality of risk management related to the banks' equity portfolio.

From a statistical perspective, VaR is a measure of the quantile of the distribution of returns, with the percentage probability that the portfolio damage [ε] is less than –VaR over a certain time span [T]:

$$P_{VAR} = P(\varepsilon < -VaR) = \int_{-\infty}^{-VaR} P_T \cdot \varepsilon \cdot d\varepsilon$$

where P_T represents the probability, distribution related to the profitability on a temporary stretch with T units.
To calculate VaR it is necessary to determine two parameters:

- Temporal extent or time horizon of the measured risk [t]: if it is calculated for the risk, it is suggested to take into account a reduced temporal extent to obtain a result as relevant as possible, and if it is determined in order to establish capital it is proposed to use an extended time interval.
- It is suggested that the confidence probability [p] be within the range of 95-99%, otherwise the relevance of VaR will be altered.

With the evolution of statistical modeling, among the banking institutions it was noticed the increase of the use of econometric models in order to quantify the market risk. In order to identify through the VaR method the possible loss related to a portfolio, it is necessary to fulfill the following aspects:

- Determining the risk elements that can alter the bank's portfolio
- Realization of risk scenarios in order to simulate them both in the hypothesis of normal market conditions and in the hypothesis of extreme conditions
- Determining the time frame for holding the assets related to the portfolio
- Determining the degree of confidence in measuring the damage
- Loss distribution measurement
- Identification of VaR distribution through various econometric models and techniques

VaR represents the value resulting from differentiating the expected value of the portfolio at the selected time span [t] with the respective probability [p], and the minimum value of the portfolio that is offered by the distribution quantile, for the same [t], respectively the same [p], thus:

$$\mathrm{VaR} = V_m - V_q = V_0(1 + R_m) - V_0(1 + R_q) = V_0(R_m - R_q)$$

$V_0 \leftrightarrow$ the value of the portfolio at present
$V_m \leftrightarrow$ the average expected value of the portfolio over time t
$V_q \leftrightarrow$ the minimum possible value to be recorded (quantile) by the portfolio over the selected time frame, corresponding to the confidence interval
$R_m \leftrightarrow$ average return on the portfolio over time t
$R_q \leftrightarrow$ quantile yield

Minimum return on portfolio for the selected time frame [t] with probability [p] is established starting with the distribution function:

$$1 - p = P(x < R_q) = \int_{-\infty}^{Rq} f(x)dx$$

We admit that profitability is characterized by the law of normal distribution, so the probability density function is:

$$f(x) = \frac{1}{\sigma\sqrt{2\pi}} \cdot e^{-\frac{(x-\mu)^2}{2\sigma^2}} \quad ; \quad x \in (-\infty, +\infty)$$

The distribution function is: $F(r) = \int_{-\infty}^{r} f(x)dx$, estimating the possibility of a value less than r for the random variable. A standard distribution is characterized by:

- Zero average ($\mu = 0$)
- Unitary variance ($\sigma = 1$)
- Distribution density function: $\varphi(x) = \frac{1}{\sqrt{2\pi}} \cdot e^{-\frac{x^2}{2}}$

The standard distribution is created by transforming the normal one using $= (z - \mu)/\sigma$, with z random variable of normal distribution[$x \approx N(0,1)$]

Portfolio yields will comply with the normal distribution law:

$$1 - p = P(x < R_q) = \int_{-\infty}^{R_q} f(x)dx = \int_{-\infty}^{\alpha} \varphi(z)dz$$

$\alpha = \varphi^{-1} \cdot (1 - p)$, α the maximum permissible value of the tolerance threshold

$$\alpha = \frac{R_q - R_m}{\sigma} \quad => \quad R_q = \alpha \cdot \sigma + R_m$$

We return to the initial VaR formula and by replacing the above relations in the expression we will obtain:

$$\mathrm{VaR} = V_m - V_q = V_0(R_m - R_q) = V_0[R_m - (\alpha \cdot \sigma + R_m)] = -V_0 \cdot \alpha \cdot \sigma$$

- σ = portfolio volatility

At first view, we notice how increasing the volatility of the portfolio will generate a higher value for VaR. If the horizon of ownership is limited, changes in average returns will not significantly influence VaR results, however if the horizon of ownership is long the changes in average returns are considerable. We also notice how the increase in VaR is directly related to the increase in confidence.

Results and Discussions

The increased volatility of financial markets over the past decade has led researchers and regulators to design and develop more sophisticated risk management tools.

The basic measure currently used by financial analysts to quantify market risk is to apply the value at risk methodology. Value at Risk is defined as the maximum potential loss of a portfolio's value, for a given probability, caused by adverse behaviors that may occur in the market.

The calculation method reduces the market risk associated with any portfolio to a single number, the loss associated with a given probability.

The VaR methodology can have many applications and is used both for risk management and for regulatory purposes.

For example, the Basel Committee on Banking Supervision requires financial institutions to meet capital requirements based on VaR estimates. If the underlying risk is not estimated correctly, this can lead to a sub-optimal capital allocation, leading to consequences on the profitability or financial stability of institutions.

The approach of this case study will be made in the context of the Basel III Agreement and involves, in the first part, the estimation of market risk in the analysis of the currency positions of a portfolio. The following two aspects need to be clarified: “long” and “short” positioning. These are two terms used by investors when they want to define their position in the market when they want to trade an asset.

When you position as a long-term investor, you buy the asset and expect it to increase in value and then make a profit from the sale of this asset. For example, consider the USD-EURO parity with the ratio 1 USD = 0.907 Euro (according to the exchange rate from November 23, 2019), i.e. we say that we trade $ 1 on the market, on November 23, against the euro at a ratio of 0.907. If position as a long-term investor, this means that we expect the dollar to rise against the euro and then, let's assume that I will buy 2000 USD at the price of 0.907 euro / dollar. So, we invest the amount of 1814 euros to buy the amount of $ 2000.

If the prediction was correct, after a certain period of time, let's say that after 1 month, the ratio between the dollar and the euro will reach 1 euro = 1 dollar. So, the $ 2,000 I bought 30 days ago is now worth the equivalent of $ 2,000 and I decide to sell it. Now the 2000 dollars are no longer worth 1814 euros, but 2000 euros, thus, by assuming the long position of the dollar against the euro we won 186 euros (2000 euros - 1814 euros).

If you position as a short-term investor, stock will be for sale and will expect the value of my assets to decrease in an assumed time frame. I will use the example above, but adapted to the short position. Therefore, sell the amount of 2000 dollars at the price of November 23, 2019 and buy with them the amount of 1814 euros. If our forecast was correct, then after the period of 1 month the dollar will decrease against the euro and our assume that it will reach the ratio of $ 1 = 0.807 euro. Therefore, the 1814-euro bought with 2000 dollars I will sell to buy dollars with the amount obtained. Thus, will buy back the amount of 2248 dollars, so we get a profit of 248 dollars.

The VaR methodology has the role of assessing and determining the total risk of a portfolio of financial assets. The value at risk measures the maximum potential loss, likely, to be obtained at a certain position or for a certain portfolio of positions, for a certain period of time and with a certain confidence interval (99% or 95%).

Therefore, we propose the following case study. It is considered that it is desired to make an investment in a portfolio of currencies described in the table below. The first steps regarding this methodology are the identification of short and long positions and the construction of the database by identifying the exchange rates, for the analyzed period.

Table 1: Database with value position, long position, short position, net position and exchange rate

01.12.2019					
Currency	Exchange rate	Value position	Long position (LP) (RON)	Short position (SP) (RON)	Net position (NP) RON
EUR	4.7781	1000	0	4778.1	29503
USD	4.3425	2000	0	8685	
CHF	4.3443	3000	0	13032.9	
GBP	5.5999	10000	55999	0	

The investor is positioning long for GBP and short for EUR, USD and CHF. The table above describes the values of the exchange rate relative to the national currency of Romania for a period of 9 days.

As you can see, the net position is RON 29.503.

In the table below we have described the net foreign exchange positions calculated as value according to the following formula:

$$NP = \sum LP - \sum SP$$

Table 2: Database with currencies for analyzed period

Currency	19.11	20.11	21.11	22.11	25.11	26.11	27.11	28.11	29.11
EUR	4.7759	4.7776	4.7808	4.7729	4.7722	4.7765	4.7792	4.7788	4.7781
USD	4.3145	4.3172	4.3144	4.316	4.3325	4.3356	4.3422	4.3394	4.3425
CHF	4.3759	4.3776	4.3808	4.3729	4.3722	4.3765	4.3792	4.3788	4.3781
GBP	5.581	5.5732	5.585	5.558	5.5805	5.5735	5.593	5.6119	5.5999

Based on the above information, the next step in the VaR calculation algorithm for this portfolio is to calculate the daily returns for each currency in the portfolio. They can be calculated either discretely or continuously, according to the following formulas:

$$Profitability_{i,t} = \frac{Price_{i,t} - Price_{i,t-1}}{Price_{i,t-1}} * 100$$

The above formula is used for discrete time calculation, where i represents the analyzed currency and t represents the time, the analyzed period, in my case expressed in days.
The following formula is used continuously:

$$Profitability_{i,t} = ln\frac{Price_{i,t}}{Price_{i,t-1}}$$

It will also be used in this case study.

Table 3: Daily returns calculation

	EUR	USD	CHF	GBP
Data	Daily return	Daily return	Daily return	Daily return
19.11	N/A	N/A	N/A	N/A

Average R	5.11711E-05	0.0007188	5.58475E-05	0.00037564

In table 3 we calculated the daily returns, in continuous time, for each currency. The next chronological steps are the calculation of the net position and currency positions. These are presented in table 1 Long currency positions are usually marked with "+" and short ones with "-". Given that the only currency in which the agent positions itself for a long time is GBP, the investor / bank will buy this currency and expect its value to increase in the next period.

Next, will calculate the volatility for each currency in the portfolio, expressed as a square deviation.

$$\sigma_i = \sqrt{\frac{\sum_{t=1}^{T}(Profitability_{i,t} - Average\ Profitability_i)^2}{T-1}}$$

Where,

$$Average\ profitability_i = \frac{\sum_{t=1}^{T} Profitability_{i,t}}{T}$$

Table 4: Volatility calculation

	EUR	USD	CHF	GBP
Date	Volatility	Volatility	Volatility	Volatility
19.11	N/A	N/A	N/A	N/A
20.11	9.2854E-08	-9.315E-05	0.0003326	-0.0017742

29.11	3.907E-08	-4.623E-06	-0.000216	-0.0025162
sum/9	4.9604E-07	7.986E-05	6.205E-06	4.174E-05
Final Volatility	**0.0007043**	**0.0089365**	**0.002491**	**0.0064605**

The next step is to calculate the correlation coefficients for each two currencies in the portfolio and then build the matrix of correlation coefficients for all currencies in the portfolio. Thus, the correlation matrix will have the following form.

Table 5: Matrix of correlation coefficients

Correlation matrix				
	EUR	USD	CHF	GBP
EUR	1	0.0050248	0.0011	0.00324
USD	0.0050248	1	-0.00048	0.02382
CHF	0.0010995	-0.0004815	1	0.077461
GBP	0.0032401	0.0238199	0.077461	1

For the next step, we need to determine the probability with which we want to calculate the maximum expected loss related to the analyzed currency portfolio, i.e. to establish the probability with which we want to calculate Value at Risk. For the probability I use, i.e. 99%, a confidence factor of 2,326 is given.

$\mathrm{VaR}_{\mathrm{Euro}} = -0{,}078$

$\mathrm{VaR}_{\mathrm{USD}} = -1{,}805$

$\mathrm{VaR}_{\mathrm{CHF}} = -0{,}755$

$\mathrm{VaR}_{\mathrm{GBP}} = 8{,}41$

The VaR is calculated for 1 day using the risk formula for a certain portfolio according to the formula:

$$Value_at_Risk_p = VaR_daily^t * \omega * VaR_daily$$

Where ω represents the matrix of correlation coefficients and has the form:

$$\omega = \begin{pmatrix} \rho_{11} & \rho_{12} & \cdots & \rho_{1n} \\ \rho_{21} & \rho_{22} & \cdots & \rho_{2n} \\ \cdots & \cdots & \cdots & \cdots \\ \rho_{n1} & \rho_{n2} & \cdots & \rho_{nn} \end{pmatrix}$$

In the case of the analysis performed, applying the last two formulas above we obtain the following results:

$$VaR_daily^t = (-0{,}078;\ -1{,}805; -0{,}755;\ 8{,}41)$$

$$VaR_{daily} = \begin{pmatrix} -0.078 \\ -1.805 \\ -0.755 \\ 8.41 \end{pmatrix}$$

$$\omega = \begin{pmatrix} 1 & 0.005 & 0.001 & 0.003 \\ 0.005 & 1 & -0.0004 & 0.023 \\ 0.001 & -0.0004 & 1 & 0.077 \\ 0.003 & 0.023 & 0.077 & 1 \end{pmatrix}$$

So,

$$\mathrm{Value}_{\mathrm{at}_{\mathrm{Risk}_\mathrm{p}}} =$$

$$= (-0{,}078;\ -1{,}805; -0{,}755;\ 8{,}41) * \begin{pmatrix} 1 & 0.005 & 0.001 & 0.003 \\ 0.005 & 1 & -0.0004 & 0.023 \\ 0.001 & -0.0004 & 1 & 0.077 \\ 0.003 & 0.023 & 0.077 & 1 \end{pmatrix} * \begin{pmatrix} -0.078 \\ -1.805 \\ -0.755 \\ 8.41 \end{pmatrix}$$

$$\mathrm{Value}_{\mathrm{at}_{\mathrm{Risk}_\mathrm{p}}} = 72.93 \text{ RON}$$

The last step in the VaR calculation methodology for a currency portfolio is the calculation of the VaR for the portfolio consisting of the four currencies, over the analyzed time horizon, of 9 days. It is calculated according to the following formula:

$$\mathrm{VaR}_{\mathrm{p,T}} = \mathrm{Value_at_risk}_\mathrm{p} * \sqrt{\mathrm{T}}$$

$$\mathrm{VaR}_{\mathrm{p,9}} = \mathrm{Value_at_risk}_\mathrm{p} * \sqrt{9} = 72{,}93 * 3 = 218{,}80 \text{ RON}$$

Table 6: Value at Risk of entire portfolio

Value at Risk	
VaR for 1 day	72.9358192
T	9
Probability	99%
Confidence factor	2.326
VaR for portfolio	218.807457

The result of the analysis was summarized in the table above. In the analysis performed, it was forecast with a probability of 99% that will be the maximum loss of the value of the portfolio generated by a possible appreciation of the national currency, on 01.12.2019. The VaR was calculated for each currency held in the portfolio and then the matrix of the correlation coefficients between the daily returns of the currencies held in the portfolio. We can conclude that if the currency will appreciate at the above date, the maximum value of the portfolio loss will be 218.8 RON.

The correct interpretation and implementation of the methodology in a clear and well-structured way makes these analyzes beneficial in analyzing the performance of an asset portfolio. Any predicted shock that could exist on the market can be predicted a value of the expected loss. Depending on this value, an agent or a bank can identify certain methods of adjustment and self-regulation so that the loss is reduced or even avoided. Any change can create a systemic risk in the network of financial markets and can have negative effects on banking institutions. As a method of regulation and self-regulation at the level of financial institutions, respecting the BASEL regulatory framework, banks use certain tests that introduce certain shocks. One of these tests is the stress test VaR with the help of which certain scenarios are made. The GARCH model and Monte Carlo simulation are used to build the stressed portfolio.

Conclusions

Financial stability is one of the most important means of reducing economic uncertainty that influences decision-makers in their establishment and investors on long-term investment funds. Financial resilience needs to be assessed in terms of its ability to absorb shocks, protecting countries from making costly short-term adjustments in the real economy through employment or inflation adjustment. Finding a balance between financial stability and the resilience of the financial system, two competing objectives, is a critical path for decision makers.

This paper highlights the importance of estimating potential loss through the VaR methodology which is a means of representing, where appropriate, an alarm signal. Extending the thinking on this application, we must look from the perspective that this alarm signal can be identified as a systemic event that can spread to an entire financial network. In an uncertain environment, surrounded by a lot of information, the evaluation of systemic events and the measurement of the severity of a network is an extremely sensitive subject and must be approached with great care from all perspectives.

The economic system at national or global level can be seen as a complex network characterized by all the activities that are undertaken by the agencies and the economic units that make it up.

The stock market, as an important component in an economic system, plays a very important role because it is a trading environment that is closest to the model of a perfectly competitive market respecting the following specific features: atomicity, homogeneity, transparency of information, entry and free exit from the market and mobility of factors of production.

This research proposes an analysis of the market risk approached through the VaR methodology applied on a currency portfolio in order to analyze its performance. A high value of VaR can be an alarm signal because it can be identified as a systemic event that can spread to a banking network.

It is important to study and understand the dynamic and adaptive behavior of the financial market because two players or actors of this system may have different behaviors regarding investment decisions and this behavior may affect the evolution of the market.
Behavioral economics provides an ideal framework for understanding when and how agents make mistakes and how they or systematic biases predictably occur under certain conditions or circumstances. The concepts offered by this field can be used to build environments that encourage people to make wise decisions, taking into account the dynamic environment in which their actions are performed.

After investigating these elements presented above, a correct risk management on the investment market is a current topic, of interest both for specialists in the field and for potential investors.

Actions Taken by Public Companies in Favor of Corporate Social Responsibility – a Polish Case

Anna MATUSZEWSKA

Calisia University-Kalisz, Poland
a.matuszewska@akademiakaliska.edu.pl

Abstract

In the publication by Bowen called Social Responsibilities of the Businessman, which became the first complex discussion about business ethics and social responsibility, a need to run a company taking into account needs of a given company's surroundings, was mentioned for the first time. [Bowen 1953]. According to the concept of corporate social responsibility, an entrepreneur who functions in a certain social and natural environment, cannot disregard its needs and interests. As Bowen notices, decisions made by entrepreneurs have a direct influence on the life of people in a society. The main aim of this article is to give an answer to the question if endeavours made by public companies fall into the category of corporate social responsibility. The more detailed aim is an endeavour to answer the question if taking this type of actions is treated like a sense of responsibility or a need? The article concentrates on giving an overview of critical activities of a selected company in recent years paying special attention to the period of COVID 19 epidemic. In order to achieve the aforementioned goal, a thorough analysis of special literature was carried out as well as unstandardized techniques of direct interviewing were applied. In addition to the above, both monographic method and the method of studying source documents were used in the article.

Keywords: Corporate Social Responsibility; Quality Management, Prosocial Actions, Ecology, The Health Of The Local Community, COVID 19.

Introduction

One of the most fundamental spheres of human activity and society activity is business activity, and running a business is possible, mainly thanks to cooperation with other people. That is why the functioning of companies in societies means that they should not behave in a discretionary way, it is their duty to follow proper norms of conduct, which is inseparably linked with responsibility [Rogowski 2016]. In the opinion of Drucker „…each business organization takes full responsibility for its influence on local community and societies, in which they function" [Drucker 1999]. CSR can support the financial side of running a company over the long term, so it can bring in not only social but also financial profits by strengthening a company's reputation, building up organizational culture based on ethical conduct [Windsor 2001].

Therefore, it seems justified to carry out an analysis in this scope, because apart from economic aspects, companies function in the specific legal, ethical and even esthetical aspect. Research on public companies activity within the scope of CSR was done on the example of Waterworks and Sewage System Company PLC in Kalisz (in Polish the company is called Przedsiębiorstwo Wodociągów i Kanalizacji w Kaliszu spółka z o.o.). For the needs of this article the author decided to use the abbreviation for the full name of the company, which goes as follows: PWiK or PWiK Kalisz). The main sources of information were the analysis of source documents and getting information during direct interviews with the board and employees.

The subject under study determined and effectively carries out the mission depending on delivering waterworks and sewage system services to the citizens of the town and surrounding districts, out of concern for the high standard of their life and a good condition of the natural environment, based on modern company model orientated to the needs of its clients. [Source documents PWiK Kalisz].

For more than 70 years of functioning, the company located in Kalisz have adopted various organizational form, changing its scope and range of actions. In 1938, Waterworks and Sewage System Company and local Gas Company merged to form one, united company. In 1952 Town's Public Utilities were set up. Its activity covered cleaning services of the town, squares, hotels, public communication, production and delivery of gas and waterworks and sewage systems. Since 1st January 1954, following the separation, Town's Public Utilities No 2 were set up. Gas

Cite this Article as: Anna MATUSZEWSKA "Actions Taken by Public Companies in Favor of Corporate Social Responsibility – a Polish Case" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Company and Waterworks and Sewage System were included in the above public utilities. The given solution remained unchanged until the end of 1963. In January 1964 there was a separation of Gas Company and Town's Public Utilities No 2, as a result of which Waterworks and Sewage System Company in Kalisz was set up. Next years saw organizational changes, and as a result of the Town Council Resolution in Kalisz that was passed on 3rd December 1991 and as a result of the notary deed of 3 December 1991, Waterworks and Sewage System Company PLC in Kalisz was founded. The company adopted this organizational form on 1st January 1992, and organizational changes, as well as the investment strategy that was adopted, resulted in the dynamic development of the company. Actions aimed at improving water quality and its efficient distribution, organization of sewage management and professional customer service have been the fundamental goals of the company's management and employees for the last decade and they remain a priority. Four water treatment stations that were built at that time enable production according to all domestic and the EU norms, and all water that is produced and delivered to customers undergoes treatment process. In order to ensure the effectiveness of water delivery by improving pressure parameters in the waterworks system, all water pumps were modernized. The use of automated systems regulating pressure enabled pressure stabilization in the system. Parallel with the above, starting a monitoring system of the water treatment station and the pumping house, created the possibility of full control over all those objects. PWiK Kalisz extracts and treats almost 5 millions cubic meters of water, providing its services in the area of 132 ha, where six water intakes, four treatment stations, 12 tanks for pure water, 8 mains pump houses and sewage pump houses are located: the main pump house on Złota Street, and over 90 local pump houses, two administrative objects and many kilometres of underground infrastructure. The company employs 145 people, who everyday care for water delivery to each flat and sewage outflow to water purification plant without any obstacles. In order to ensure water delivery with proper pressure and quantity, 70 water pumps and about 100 sewage pumps work every day.

The main goal of this article is to point out and carry out analysis and evaluation of actions taken by the company under study in order to promote corporate social responsibility. On the grounds of the range of this issue, a decision was made not to take into consideration issues regarding the company's employees, however it should be pointed out that creating very good and safe working conditions for the staff was appreciated many times in the form of awards and distinctions.

One research question remains, namely to what extent actions taken by PWiK influence the quality of services, clients' satisfaction, health of the local community and the company's image? Additionally, there is a question if actions that are taken to promote corporate social responsibility are treated as a responsibility or a need?

Literature Overview

Roots of corporate social responsibility date back to ancient times, when great philosophers such as Aristotle were differentiating between the condemned „art of making money" and „the art of managing" [Arystoteles 2001]. However, referring to descriptive definitions, the literature usually shows the 1950s, where Bowen (1953) - who is said to be „founding father" of CSR - determined corporate social responsibility as an entrepreneurs responsibility to adopt such policy and take such decisions, which are desirable by a given society on account of goals and values. [Bowen 1953]. It was C. Walton (1967), who claimed that the concept of social responsibility articulated by the close relationship between society and companies. By contrast, G. Steiner (1971) took the view that business is and must remain a basic economic institution but also takes an obligation to help society in reaching its basic goals [Rojek-Nowosielska 2017]. Freedom to realize prosocial actions is one of the critical aspects presented by H. Manne and H. Wallisch (1972). The very idea of the above attitude is that none of the actions is legally imposed on entrepreneurs [Manne and Wallisch 2020].

World Business Council For Sustainable Development defines corporate social responsibility as „ continuous responsibility of business regarding ethical behaviour and contribution to economic development while improving the standard of living of workforce and their families and local society and the whole of society at the same time" or as „responsibility of a business to contribute to sustainable economic development, cooperation with employees, their families, local community and the whole of society in order to improve the standard of their lives"[The World Business Council for Sustainable Development 1998]. It is worth quoting a definition formulated by R. Lea (2002), in which the author touches upon the aspects of caring for the natural environment. „Corporate social responsibility of businesses regards business and other organizations that are beyond scope of responsibilities resulting from legal regulations, in order to manage the influence those businesses and organizations have on environment and society. It especially concerns the way of interactions with employees, suppliers, clients, local community, and the range of actions, which are taken to protect the environment" [Rojek-Nowosielska 2017].

Managing company should take into consideration aspects of environmental protection, which are crucial from the social perspective. It should be stressed that environmental protection is not an aim in itself - the goal is a better standard of living, which can be influenced by environmental cleanliness, health conditions, the beauty of the scenery,

access to natural resources. It is the quality of life as the most important good that requires being included among social aims of environmental protection [Adamczyk 2009]. The presented overview shows only certain literature definitions and is not complete, according to Rok, there are at least several hundred definitions of CSR in the specialist literature [Rok 2013]. The emphasis was put on selected basics of relations and scopes of interest. The notion of corporate social responsibility is continuously evolving, and together with this evolution change the determinants influencing and shaping this notion. For the needs of this monograph, the author claimed the regulations included in ISO 26000 standards to be the prominent ones, the regulations that are the result of consultations that were carried out in the environment of clients, representing 300 institutions from 66 countries and allowed to determine the status of this standard, which acts as a guide containing directives and recommendations and within the scope of social responsibility. According to ISO 26000: „Responsibility for making decisions and taking actions that have an influence on society and environment, realized by transparent and ethical behaviour, in conformity with sustainable development and social wellbeing, including the needs of clients, in conformity with the law and international norms of behaviours, integrated by an organization and used in actions, is called social responsibility [ISO 2020].

The analysis of actions taken by PWiK Kalisz

PWiK in its current actions spares no efforts to be a good employer, a customer-friendly company and a good neighbour. The company takes actions in favour of corporate social responsibility by functioning in an ethical and responsible way towards various interested groups, above all towards the employees, local society and the natural environment - the so-called „silent interested party" [Source documents PWiK Kalisz]. Being socially responsible means investing in human resources, environmental protection, relations with the company's surroundings and informing about those actions. All the aforementioned aspects lead to the company's increase in competitiveness and to shape conditions for sustainable social and economical development [PARP 2020].

Constant actions to the continuous improvement of water quality from the health aspect

The citizens of Kalisz are supplied with water coming from deep-well, Quaternary and Jurassic sources. Quaternary waters are characterized by a low mineralization, medium hardness, increased content of iron compounds and manganese. The reaction of the water solution is slightly neutral. On the other hand, Jurassic waters belong to medium-hard category waters with a neutral or an alkaline reaction of the water solution, and are characterized by natural smell, medium mineralization, and often contain unstandardized levels of iron and manganese compounds [Source documents PWiK Kalisz]. PWiK has underground water intakes called „LIS", 42 Quaternary infiltrating drilled wells, underground Jurassic water intake located on Fabryczna Street 1 drilled well, underground Jurassic water intake located on Poznańska Street 1 drilled well, underground Jurassic water intake located on Warszawska Street 1 drilled well, underground Jurassic water intake located in Szeroka Street 1 drilled well, underground Quaternary water intake 1 drilled well.

Water like food should deliver valuable nutrients. Drinking water has a positive influence on an organism by delivering valuable micro and macro elements, it also supports good metabolism. Water from drilled wells that is available in Kalisz belongs to the category of waters characterized by low or medium mineralization. Thanks to drilled intakes (Tertiary and Quaternary layers) water purification process is obtained in a natural way without using chemical substances. Only the excess of iron and manganese compounds is removed from water during the treatment process. It is also worth noticing that water is disinfected with UV rays. Thanks to that no chemical compounds containing chlorine are used, water is free of bad smell and taste [Interview with Production Manager at PWiK Kalisz]. Safety and quality of water have fundamental meaning for the development of well being in people. World Health Organization makes global endeavours to prevent transmission of diseases in water [WHO 2020]. The quality of water in Kalisz is controlled by the accredited laboratory. The water must satisfy quality requirements in the bacteriolytic and physicochemical range, which are included in Health Minister Order on 7 December 2017, position No 2294 „On water quality to be consumed by people". Table 1 shows the results of water quality measurement in the second half year of 2019. All water parameters under research are within the limits that are acceptable by the regulations.

Table 1. The quality of the produced water in the second half year of 2019

Source: [PWiK Kalisz].

Access to safe potable water is necessary for health, basic human right and it is an element of effective health protection policy. In some regions, it was indicated that water supply investments and sanitary devices can bring net economical benefit. It results from the fact that the reduction of unfavorable health complications and costs of health care outnumbers the costs of investments that were made or actions that were taken [WHO 2017].

Promoting drinking tap water and prosocial actions

Water that is available in Kalisz is characterized by good quality, and because of that PWiK continuously encourages citizens to drink tap water and promotes a healthy lifestyle by organizing the action called „Healthy water from the waterworks in Kalisz". This action has been organized for a couple of years now and involves taking a lot of actions. Tap water is present during numerous meetings, conferences and other events, encouraging people to drink it. The participants of the night half marathon called „Bursztynowa Helena", XVII military picnic and Triathlon Kalisz organized in September 2019, were given tap water by PWiK employees. The company supports the organization of sports events in a town and at work (cycle races, shooting competitions, angling competitions) and promotes a healthy lifestyle and continuously encourages to drink water, which is necessary for our organisms.

On a daily basis, the company runs educational campaigns. The campaign, which is worth noticing and which has been run by the company for a few years and enjoys real popularity especially among primary school students and high school students is called „Where do the citizens of the City of Kalisz get water from?" In 2015, 314 people participated in this form of education, in 2016 - 281 people, in 2017 - 387 people, in 2018 - 312 people, in 2019 - 262 people. During the meetings, the participants get to know about a lot of interesting information, for instance about disinfecting water with UV rays. Each of the four water treatment stations in Kalisz and the pump house, is equipped with UV lamp. Thanks to UV technology, which is based on a purely physical process with ultraviolet radiation (UV), with a wavelength of 254 mm - 99,99% of all bacteria are killed. During educational meetings, one call follows the whole cycle of water production. Also, the company organizes „Open Days at PWiK Kalisz". In the opinion of the author of the monograph, a proper attitude to corporate social responsibility is a strategy of activity and understanding that actions that are taken within the range od CSR are the result of high social awareness of entrepreneur (the water board). This awareness is also connected with the process of local integration. PWiK organizes Christmas and Easter fair on its premises, invites children from schools located in Kalisz so that they can decorate Christmas tree together. It is worth noticing that among other things, the company published the winning pictures from plastic arts competition in the company calendar that is given to clients, business partners and employees. This way, the company integrates local community, informs about its actions, integrates the youngest by playing and building up awareness of drinking water. Each year on 22 March, World Water Day is celebrated, which is the most valuable liquid on Earth. Without water, there would not be any form of human existence or any other form of existence. Every year PWiK Kalisz joins the organization of conferences, symposiums, meetings, which are an occasion to pay attention to the issues regarding this area, especially climate changes. Each year UN-Water, the agency coordinating works of The United Nations regarding water and sanitary conditions, determines the topic of World Water Day answering and meeting the current and future challenges. According the definition of social responsibility understood as economic, legal, ethical and philanthropic responsibilities of a company towards inner and outer social groups (and entities), presented by A. Sokołowska, PWiK participated in the organization of the event called „Noble Christmas Box", the company handed over rehabilitation bed and other gifts for needful people. In addition to the above, PWiK also handed over cleaning and hygiene articles to Association „Beautiful Angels", Children's Commissioner for Poland and Social Welfare Center in Kalisz, the organizers of the action called „Clean Little Angel",

Pro-ecological actions

Corporate social responsibility defined in „The Green Book" as:

„the concept according to which, companies include social and environmental aspects voluntarily in their trade activities and when contacting clients and other interested parties", clearly accentuates freedom as well as social and environmental aspects [Green Paper of The European Commission on corporate social responsibility 2001].

In 2016 the board made a decision to include the installation of photovoltaic panels in the technical and economical task. The task was scheduled for completion in 2018-2019, which was in line with Development Strategy of the City of Kalisz for the years 2014-2024, where one of the strategic goals was supporting energy efficiency by increasing the percentage of green energy sources in the overall energy production. One of the ways to reach this goal is to increase investment in renewable energy sources, because both the EU policy and the domestic policy, strongly postulate diversification of those sources [Development Strategy of the City of Kalisz for the years 2014-2024 2014]. The problem of growing energy consumption coming from conventional sources and the pollution of the natural environment, which is the result of the above, is a point of departure for paying attention to the importance of renewable sources including economy and ecology [Jastrzębska 2017].

In November 2017, a contract for the realization of photovoltaic installation was signed with ML System PLC from Rzeszów. Photovoltaic panels with the power of 398 kWp were installed on three buildings belonging to the company:

- Water Treatment Station „Lis" - 182 kWp,
- Pump House on Smolna Street – 40 kWp,
- Roof of administration buildings on Faryczna Street Dachy – 76 kWp.

Acquiring electric energy from the sun requires substantial initial financial outlays. However, with growing energy prices and by taking into account ecological aspects (reduction of energy consumption from conventional sources by 500 MWh/year, a decision was made, based on the above arguments, to put this idea into practice. The photovoltaic installation started in July 2019, and since the start, it has produced 180 MWh. In the half-yearly scale, energy coming from renewable sources constituted 7.2% of all energy. Within the period of six months, taking into account financial aspect, the company managed to save up PLN 65.000 on energy bills.

The Constitution of the Republic of Poland defines the natural environment as value, which should be protected in absolute terms. Under article 86 of The Constitution, there is a direct obligation to care for the condition of the natural environment, and anyone whose actions and behaviours can lead to deterioration of its condition shall be held responsible for them [The Constitution of The Republic of Poland on 2 April 1997]. The doctrine underlines that this responsibility rests not only with an individual but also or maybe above all with companies whose actions can threaten the natural environment and cause its degradation [Skrzydło 2002]. Out of concern for „the silent interested party", the company increases the percentage of hybrid and electric cars in its car park successively. Since 2017 PWiK purchases hybrid cars with petrol engines (PB95), electric cars and cars with petrol engines that are gas-powered (CNG). The reason for those actions is growing awareness of care for the natural environment but also requirements given by the law regulations, society and the owner [The Act on Electromobility and alternative fuels on 11 January 2018]. International Organization for Standardization ISO, launched norm regarding social responsibility called ISO 2600, according to which the fundamental feature of social responsibility is the readiness of an organization to include social and environmental issues during decision-making process [PKN 2020]. PWiK as the first company in Poland, used basaltiform lining in tanks for purified water. Between 2014 and the end of 2015, four tanks for purified water with a total capacity of 12.000 m3 located on Smolna Street, were renovated this way.

Later the company built and opened a tank at water treatment station LIS, which has a capacity of 1400 m3 and was also coated with basaltiform lining. Because of great properties and long durability, basalt is widely used in sewage systems. Using this technology in tanks to store purified water is undoubtedly seen as an innovative attitude [Interview with the President of Board 2020]. Observation of tanks' use coated with basaltiform lining, allows to observe the improvement of stability of water quality, mainly because such type of lining is extremely resistant to abrasion and high-pressure cleaning. Additionally, thanks to chemical resistance, which causes self-cleaning of tanks, it is possible to avoid excess deposits of manganese and iron on the walls and on the bottom of tanks. Thanks to the above actions, water that is stored in the tanks for citizens of Kalisz is of better quality [Anczykowski 2019].

COVID 19

The strategy adopted by WHO for the years 2018-2025 comprises regulations regarding monitoring access to safely managed potable water services [WHO 2017]. It is an incredibly important action, especially in the face of a pandemic, which unexpectedly covered the whole world.

PWiK Kalisz operates within the scope of the legally binding regulations, and all the actions taken by the company that were presented in the article, allow to state that PWiK strives for continuous improvement of water quality as well as properly manages the process of its production. The company has implemented the systems, drawn up the procedures, instructions and programs monitoring the functioning of objects and the waterworks system and has drawn up the so-called Water Safety Plan. The subject plan determines threats and potentially dangerous events, which can affect water quality and it also contains risk assessment in case of contamination of water intakes or purification plants. Additionally, the company has the plans called Protection Plan of Objects, which includes guidelines regarding technical protection of wells, tanks or technological buildings. This plan is consulted with and approved by the Province Chief of Police in the City of Poznań. It contains accurate and detailed procedures in case of sabotage, contamination or trespassing the promises of PWiK. The company has a list of prepared plans, procedures, institutions and protective measures in order to prevent loss of health and life in case of failure, flood, blackout, contamination, sabotage or epidemic. Thanks to the above plans, among other things, it was possible to react dynamically to COVID 19. In subjects with such strategic meaning for the local community, it is necessary to assess the risk and the scale of risk immediately.

The risk assessment showed that there is very little likelihood of contaminating water with a virus, the technology is protected with UV disinfection, which kills viruses, bacterium, pathogens and fungus with almost 100% effectiveness. As a prophylactic measure during the epidemic, the tanks storing water are disinfected with chlorine. The distribution system is closed and tight, all works regarding interference in the inside of pipelines have been called off.

Currently, the company hires 145 people, 16 people are directly in charge of water production and 4 supervisory staff who do shift work 24/7. Altogether there are 20 staff members, who constitute the so-called critical staff, necessary to ensure continuity of water production. Additionally, there is a brigade dedicated to works on a network of sewage pipes and water pipes in case of failure consisting of 16 people (14 + 2 members of supervisory staff). The teams have been divided in such a way to minimize contact between employees. Special safety procedures have been implemented on the company's premises, and employees have been equipped with protective equipment. The service staff of technological objects has been divided, and sanitation of uniform, clothes, shoes, hands, objects and surfaces which employees have contact with has been implemented. Technological facilities have closed to visitors and unauthorized employees. A group of employees has been isolated, which will take over responsibilities and will be placed at water purification plants, for instance in case of a quarantine. The biggest challenge is ensuring continuity of water production, sewage management and water purification [Interview with Production Manager at PWiK 2020].

Water has to be delivered 24 hours a day to customers, it is just a basic factor next to soap, which prevents virus spread. The biggest enemy of a virus is hygiene. As research shows, washing hands with soap and water for about 30 seconds reduces the number of micro-organisms by about 90%, another 20 seconds of washing hands eliminated them altogether. Keeping any sanitary regime without water is just impossible. That is why PWiK bears a heavy responsibility in this area.

One should pay special attention to the fact that in the face of such a serious threat, which COVID 19 is, and in the face of numerous tasks, which are connected with the proper functioning of the company, the company still contributes to social actions. In order to support the realization of online studying, the company gave tablets and headsets to Special Needs Primary School No 19 in Kalisz.

Discussion

Milton Friedman - Noble prizewinner in the economy - is strongly against business participation in solving social problems. Prizewinner holds that imposing an obligation on business to fulfil social responsibilities is generally harmful to the business itself but also the economy [Rybak 2011]. However, in relation to companies providing water, the specialist literature includes opinions, which say that they should bear a special responsibility, because their actions are directly connected with using natural resources and pollution of the natural environment and also with public health. With reference to such type of activity, CSR cannot be an option but a responsibility [Zickiene, Potelis, Juozaitiene and Poteliene 2011; Brei and Böhm 2011].

Among employees (also in Poland) one can observe an increased interest in issues from the area of corporate social responsibility [Żemigała 2007]. Analyzing the results of reports by (Responsible Business Forum) Responsible business in Poland. Good practices, it can be seen that management staff more and more often and in wider scope engages in socially responsible actions, declaring that such actions are put down in the frames of strategic actions [FOB 2020].

Partnership imperative between business and society is becoming one of the most important inspirations of the concept of social responsibility. Not only are entrepreneurs expected just to deliver goods and services but also to run business activity in such a way that society deems responsible. It can be stated that since the 1930s one can observe ongoing discussions around corporate social responsibility, where questions were posed if businesses can be socially responsible in general? Does social responsibility bring business benefits? Are the limits of CSR? In the 1970s another questions were posed, for instance: Should businesses prevent pollution of the environment to a degree that is higher than the one that is required by the law? On the other hand, recent years bring questions about how to realize strategic priorities within the scope of social responsibility, at the same time maximizing benefits for business and society and how to train managers and employees so that they can adequately react to the emerging changes of social and ecological requirements? [Gasparski 2012].

The analysis of actions that were conducted in the company under research allows to state that CSR has become an inseparable part of the company's strategy. There is an open question about the realization level of the company's CSR in comparison with other companies specializing in delivering such good and services in Poland. The author is going to conduct questionnaire in the second half of 2020, which will allow to determine CSR level in waterworks companies in Poland, and then (on this basis) will recommend possible directions of development and changes.

Conclusions

The aim of this article was reached because the presented actions that were taken by Waterworks and Sewage System Company PLC fall into the category of actions aimed at promoting corporate social responsibility. The above actions

are not only perceived from marketing and economic perspective, beneficiaries are both natural persons and legal persons, who establish different types of contacts with the company. One should pay special attention to educational actions that are taken and increasing awareness of the local community regarding favorable properties of drinking water. Water quality is subject to systematic research and examination by District Sanitary Inspectorate. It allows to encourage employees to drink water directly from the tap, by presenting advantages and qualities of water in comparison with bottled water. One should give the company special credit for all actions aimed at the youngest citizens, whose aim is to increase awareness by educating and encouraging to participle in common initiatives. By initiating ecological competitions and by installing springs in schools located in Kalisz, the company shows high maturity and cares for the health of the young generation. The answer to the research question is for sure positive, without any doubt the involvement in the area of CSR influences the quality of services that are provided, client's satisfaction, the health of the local community and the company's image. PWiK Kalisz put forward a proposal of offering water to people during numerous events organized in town. It is worth outlining that PWiK participated in World Conference on Family Health, which was held on 9-11 June 2019 and gathered guests from all around the world.

The citizens of Kalisz notice and appreciate the company's endeavours and actions in favour of the local community. A good example can be water curtains installed on the Market Square where one can cool down during heat waves, fountain and springs which have become an inherent part of the cityscape. However, because of COVID 19, the start of the fountain and springs have been cancelled until further notice.

PWiK is the company that engaged in help for the needy people during COVID epidemic with great responsibility and commitment. The company reacts to needs coming from the inside and the outside of the organization, taking dynamic actions in favour of corporate social responsibility and sustainable development. On the basis of direct interviews, it seems that those actions were taken because of need and not because of obligation. It is well reflected in blood donor actions when blood is given by PWiK employees or when planting trees on the premises of Social Welfare Home in Kalisz.

Continuous strive for ensuring a high level of services that are provided and care of building up proper relations between the owner, employees, the company's clients and the town's society resulted in gaining recognition in the competition called „Fair Play Entrepreneurship". In 2001 the company received a Fair Play Statuette - the highest recognition in this domestic competition.

The pride of the company is commonly recognized position in this business line, where PWiK is classified on the in the ranking of the best waterworks and sewage systems companies in Poland.

Proper perception of CSR depends on treating it like the concept of business activity whose elements are voluntarily and consciously incorporated into the company's strategy, enriching organizational culture at the same time.

Abstract

This paper introduces the causal associations between electricity consumption and economic growth for Pakistan based on time series of annual data from 1980 up to 2016 by utilizing Johansen Cointegration testing and Granger Causality approaches. The Johansen Cointegration Testing findings proved that the cointegrating and long-run associations exist between selected variables and empirical evidence found that the relationship between electricity consumption and economic growth exist in one-way causality direction. Renewable and nuclear energy projects should be encouraged by approving the favorable energy policies. Besides, the Pakistani government needs to establish solar energy projects for electricity generation to meet the rising energy demand in the country.

Keywords: Electricity consumption; GDP growth; Granger Causality, Pakistan

Introduction

Energy has a basic and essential key function of a country for all economic sectors around the globe (Irfan et al., 2019a). The widely studied to explore the dynamic association between energy usage and economy growth in the literature for developed and underdeveloped economies around the global economy. The empirical results of previous studies varied and seem to be contradicting with the utilization of various methodologies for different countries. Thus, our research focuses on Pakistan's electricity consumption and its growth because the country is facing enormous challenges for electrification deficit and always have the problem of load shedding around the country. Consequently, the economic productivity is crippled by energy infrastructure.

CIA estimates that Pakistan is currently suffering from an immense energy shortage due to an enormous and rising population of about 49.5 M people living without electricity. 27% of the overall population has no access to electricity, from which 9% relate to people living in urban areas and 38% to people living in the rural area who have no accesses to electricity. The mounting gap between demand and supply of electricity poses huge threats to the energy sector in Pakistan.

The country is facing worst energy issues in the history and it is expected that the energy needs will double in the coming years in Pakistan. Economic growth increases with the industrialization and thus energy demand increases with the urbanization and industrialization. Pakistan has Ideal environment in aspects of temperature and humidity. Wind is the prominent renewable energy source and its industry is growing rapidly (Irfan et al. 2019b,c). Pakistan

has sufficient wind energy sources around the long coastal belt as well as in northern areas. Various techniques are being used to enhance the output power (Iqbal et al. 2019) that are very beneficial to fulfill the energy requirements. Economic sustainability can be a helpful appliance for economic growth productivity and reducing energy consumption.

The aim of the research is to identify the connection between electricity consumption and economic growth in favor of Pakistan as a developing country by employing Johansen cointegrations and Granger Causality methods for a period of 1980 to 2016. The remainder of the paper is as follows: Section 2 provides a review of the literature. Section 3 discusses the data and methodology. Section 4 discussions the research results and finally, section 5 concludes the study and offer policy recommendations.

Literature Review

The literature review suggested the connection between energy usage and economic growth related to this research. Stern (1993) examined the causality connection between energy consumption and economic growth by employing multivariate techniques in the USA. The author found that changes in energy consumptions drive to changes in the economic growth. Yoo (2006) has determined the dynamic connection between electricity consumption and per capita income in four economies, including Malaysia, Singapore, Thailand, and Indonesia over a time period of 1971 to 2002. The estimated findings indicate causality relationships of income growth and electricity consumption is uni-variate for Indonesia and Thailand while a bi-variate causality exist for Malaysia and Singapore.

Ciarreta & Zarraga (2010) have employed the Panel cointegration tests for Denmark and Finland to investigate the panel causal association for GDP growth and electricity access form periods of 1971 to 2001 and estimated direction of causation running from electricity access to GDP growth in nations. Oh and Lee (2004) have conducted to verify the association between uses of energy and GDP growths from 1970 to 1999 in South Korea and findings denote that two-way causations occur among the use of energy and GDP growths in a long-term period, whereas for the short-term period, there is one-way causation occurs for both variables. Shahbaz & Lean (2012) have concluded the dynamic link among electricity use, economic factors with a factor of production by applying cointegration causality tests for Pakistan. The estimated outcomes expressed that two-way causality directions found amidst electricity use and GDP growth in Pakistan.

Baranzini et al. (2013) have utilized the ARDL bounding testing approach to identify the cointegrating association amidst electricity consumption and GDP growths for Switzerland for a time period of 1950 to 2010. The results denote long-run relationships amidst electricity consumption and per capita GDP in Switzerland. Apergis & Payne (2009) have demonstrated to examine panel causal association for electricity consumption and economic growth in Commonwealth nations from a period of 1991 to 2005 by applying panel cointegrating approach and empirical evidence denote the causality of cointegration relationships of electricity use and economic growth is in one-way direction for both said variables. Karanfil & Li (2015) have employed Pedroni Panel Cointegration method to demonstrate the connection among electricity consumption, urbanization and economics factor for 160 developing and developed nations from the period 1980 up to 2010 and empirical outcomes represent the mixed results among variables in 160 nations.

Methodology and Data

This study examined the association between electricity consumption (LELC) and economic growth (LECG) in the form of logarithm in favor of Pakistan with time series annual data from a period of 1980 to 2016. Electricity consumption is measured in KWh, while economic growth is measured in GDP per capita (US$). All the data obtained from World Bank Indicators (WDI, 2018). Firstly, we have employed the Augmented Dicky-Fuller (ADF) method of unit root tests to verify the integrated order of one I(1) or zero I(0) between these research variables. Secondly, we have employed the Johansen Cointegrations framework to examine cointegration relationships among research variables and finally, we have utilized Granger Causality technique to investigate the direction of causality for said variables. The equation of the log-linear model expresses as:

$$lnELC = \delta + \rho_1(lnECG) + \mu \qquad (1)$$

Here,

- ln: indicates the natural logarithm
- ELC: indicates the electricity consumption
- ECG: indicates the annual GDP growth rate
- μ: indicates error term

Results and Discussion

The purpose of this research is to determine the associations between electricity consumption and economic growths over the periods of 1980-2016 in Pakistan. Times series data are typically strived not to be stationary, so spurious results may be implied by the estimated regression results.

In addition, to evaluate the order of integrations for these variables, unit roots tests are applicable to solve the stationary problem. Still, we employed the ADF test at first differences and level. The estimated findings of ADF denotes that the selected variables are not stationarity at level, but all selected variables are stationarity at first differences; it means that our model is stationary at integration orders of one I(1) which is described in Table 1

Table 1: ADF results of unit roots test.

Variables	**Level**		**First difference**	
	Intercept	Intercept and trend	Intercept	Intercept and trend
LELC	-1.68524	-0.65849	-6.41763***	-6.36514***
LECG	-4.87284	-4.76248	-6.97463***	-6.86235***

**** denotes the Significant at first difference level, respectively.*

Having the research variables in the model are stationarity in the integrating order one I(1), we can apply (Johansen, 1988) Cointegration model to evaluate the long-run association among electricity consumption and economic growth rate. The estimated outcomes of Johansen's cointegration conferred into trace statistic and maximum eigenvalues. The Johansen cointegrating approaches represent that these variables LENC and LECG are more than two cointegrating equations and rejected null hypotheses at 5% significant level described in Table 2 and Table 3. Therefore, we concluded that the cointegrated and long-run association's existence in selected variables. We have also used the VAR method to calculate the optimum lag lengths for Johansen cointegration approaches proceeding from AIC and SC criteria to support lag 1 interval for both series at first differences.

Table 2: Johansen Cointegration results trace statistics.

Null hypothesis	**Eigenvalue**	**Trace statistic**	**Critical value (0.05)**	**Prob.****
None *	0.519	32.397	29.797	0.005
At most 1*	0.434	21.681	15.494	0.036
Max-eigenvalue test indicates 2 cointegrating eqn(s) at the 0.05 level				
* denotes rejection of the hypothesis at the 0.05 level				
**MacKinnon-Haug-Michelis (1999) p-values				

The cointegrating associations occurred between research variables. Then, we can be applied Granger causality test to check the causal direction between selected variables expressed in Table 4. The analytical results indicate that there is uni-variate causal direction between economic growth and electricity consumption and outcomes indicate the direction of causality running from electricity consumption to economic growth.

Table 3: Johansen Cointegration results for max eigenvalue

Null Hypothesis	**Eigenvalue**	**Max eigenvalue**	**Critical value (0.05)**	**Prob.****
None *	0.519	25.716	21.131	0.004
At most 1*	0.434	21.681	15.494	0.051
Max-eigenvalue test indicates 2 cointegrating eqn(s) at the 0.05 level				
* denotes rejection of the hypothesis at the 0.05 level				
**MacKinnon-Haug-Michelis (1999) p-values				

Table 4: Results of Granger Causality

Null hypothesis	Obs	F statistic	Prob.
LELC does not Granger Cause LEG	35	8.01785	0.0027
LEG does not Granger Cause LELC	35	0.95388	0.4596

Conclusion and Policy Recommendation

The paper determined the causality association between electricity consumption and economic growth from 1980 to 2016 in Pakistan. In this study, we have applied unit root test i-e Augmented Dicky-Fuller technique (ADF) to scrutinize the stationarity between selected variables, applied Johansen cointegration technique to determine cointegration association between the research variables and used Granger causality test to investigate the causality direction among the selected variables. The estimated consequence of ADF test shows that the selected variables are stationary at first differences which mean that we can apply the Johansen cointegration test. The outcomes of the Johansen Cointegration method indicate that relationships of cointegration existing among the selected variable. Finally, the Granger causality reveals that the relationships between electricity consumption and economic growth occur the one-way causality direction, which means that the direction of causality running from electricity consumption to economic growth, it confirms that there is electricity consumption and economic growth, are strongly correlated in Pakistan.

The policy implication of the paper is that Pakistan will also need to invest more heavily in the sectors of energy; including coal, gas and hydroelectric power, thus further increasing its current account to reduce the import pressure (Irfan et al., 2020,2021). The government needs to develop solar energy projects to produce electricity to meet the rising energy demand in the country. Even though, the Government of Pakistan should implement new nuclear power plants to fulfill energy demand in the country.

Annotation

The article is devoted to the study of the impact of various types of innovations on sustainable development of industrial companies. The empirical analysis is based on data from 123 industrial companies (167 respondents). For the analysis, factorial and regression methods were used, which makes it possible to assess the dependence of various types of innovations on the enterprise efficiency. Within the framework of this study, three resultant indicators of industrial companies sustainable development have been distinguished: the share of sustainable products in the total output, the level of reduction in resource consumption, and the development of qualified employees.
This approach made it possible to conduct a comprehensive analysis of innovation activities and analyze the impact of each type of innovation on the industrial enterprises sustainable development indicators.
The obtained results showed: (1) all types of innovations at enterprises are interconnected: product and technological innovations are positively interconnected with management innovations, and the intensity of management innovations leads to organizational innovations, (2) the increase in the sustainable products share is more influenced by product and technological innovations, resource consumption reduction - with technological and organizational, and qualified employees development – with managerial innovations.
The conclusions made will allow industrial enterprises, depending on their strategic goals, to combine investments in certain types of innovative activities and thereby achieve the goals of sustainable development. Understanding the complex nature of innovation will enable businesses to build long-term competitive advantages.

Keywords: Innovation, Product Innovation, Technological Innovation, Organizational Innovation, Managerial Innovation, Sustainable Development, Industry

Introduction

In recent years, an increasing number of companies around the world have voluntarily adopted and implemented a wide range of sustainable development practices in response to emerging environmental, social and governance stakeholder expectations and concerns. At the same time, they are trying to integrate the principles of sustainable development into their strategy, business models and business processes (Lisovsky A. L., 2019).

There are discussions in the literature whether the implementation of the principles of sustainable development serves the achievement of strategic goals and can lead to high financial performance or is it a necessity that will ensure the survival of the company, but will not become a source of sustainable competitive advantage?

Some studies claim that the principles of sustainable development are being implemented in companies as “business as usual” and may not be a sufficient condition for creating a competitive advantage. For example, some companies use environmental, water or waste management systems to lower costs and thus improve their efficiency. But it is unlikely that this allows companies to achieve sustainable competitive advantage, since competitors can easily implement similar systems (for example, Bakkari M., Khatory A., 2017; Posen and Martignoni, 2018). Thus, when the imitator copies the practice of a company, their profitability converges (Posen and Martignoni, 2018) and is likely to decline.

Linder “ The Impact of Different Types of Innovation on Sustainable Development: An Empirical Study of Industrial Companies” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Other studies, by contrast, claim that sustainability principles can provide a unique competitive advantage and therefore lead to better company performance. However, in order for the sustainable development strategy to create a unique competitive advantage, it is necessary to introduce innovations. At the same time, different types of innovations affect the companies performance in different ways. In this regard, the purpose of this article is to study the impact of different types of innovations of industrial enterprises on performance, expressed in terms of sustainable development.

As part of the study, 16 in-depth interviews were conducted with industrial companies representatives, and then a direct empirical test was carried out on a sample of 123 industrial enterprises (167 respondents).

The article is structured as follows. The first section describes the types of innovations and studies of their impact on the performance of companies. The second section describes the research methodology, data collection and econometric models used for analysis. The third section describes the research results obtained and formulates recommendations for their application in practice. In conclusion, the obtained results are summarized.

Theoretical Foundations and Research Hypotheses

Types of innovations and approaches to their classification

According to many researchers, innovation is a source of sustainable competitive advantage and growth for organizations (see, for example, Abdikeev N.M., Bogachev Yu.S., Losev A.A., Tolkachev S.A., 2019; Faiazova S.I., 2020, etc.). The classic typology of innovation is the classification proposed by the OECD. According to this typology, there are five types of innovations[1].

The first type is product innovation, which is understood as goods or services that have fundamentally new or significantly improved properties associated with technical specifications, materials used, consumer value or other functional features. The main trends in the field of product innovation research, discussed by researchers in the last 2-3 years, are: the introduction of new technologies (Internet of Things, Big Data analytics, 3D printing) to create innovations consistent with the concept of Sustainable Development; the use of open innovation tools to create value together with consumers; product innovation in emerging economies.

The second type of innovation is technological (process) innovation, which are new elements introduced into production, organizational or service improvements, improved materials, production process and equipment, as well as improved IT products in order to achieve lower prices and / or higher quality of product. Basically, technological innovation is considered as a source of product, and vice versa, product innovation creates a need for technological improvements in product production. Recent works investigate the possibilities and benefits of implementing lean manufacturing methods in order to increase value for customers [Arsenova E.A., Nikolaeva T.Yu., 2018].

The third type of innovation is marketing innovation, defined as the development of new methods for promoting a product, a new way of pricing, and a new packaging or type of product. They also include new methods of logistics and transportation of goods.

The fourth type, organizational innovation, represents "the introduction of a new organizational method in the company's business practice, workplace organization, or external relations." [2]

The fifth type - managerial innovations, consists in the development of new approaches and methods for motivating and rewarding employees, changing the organization's management processes, approaches to strategy formation, planning, etc.

In the work [Trachuk A.V., Linder N.V., 2019], was carried out an analysis of more than 50 works that determine the types of innovations and their classification. The authors distinguish three types of classifications of innovations: innovation classification by type or area of application; innovation classification according to the degree of novelty and the level of changes; classification by the innovation features, and a fourth approach is proposed for classifying innovations - if possible, managing them.

[2] OECD Oslo manual, 3-rd edition (2005)

Research on relationship and impact of different types of innovation on performance

In the first works (for example, Milgrom and Roberts's, 1995), researchers showed that the sum of innovations has a greater impact on the company's performance than each of the types separately.

Subsequent studies have focused on two types of relationships: one area is devoted to researching the relationship between different types of innovation, the other studies the impact of different types of innovation on the company productivity.

The works of the first group of authors focus on the relationship between product, technological and management innovations. The authors of [Roper, Du, & Love, 2008] conclude that product and technological innovations are always interconnected with managerial and organizational innovations, since the complication of a product or technology requires new management methods to successfully introduce new technologies, as well as bringing new products to the market. ...

The work [Mol & Birkinshaw, 2009] reveals the relationship between product, process and organizational innovation. The authors argue that the creation and introduction of new products to the market requires a new operational organization for more effective creation and exchange of knowledge, which entails the introduction of organizational and even managerial innovation.

Authors [Martínez-Ros & Labeaga, 2009] investigate the relationship between product, technological, managerial and marketing innovation. Based on data from 1,275 French and 3,028 Spanish firms, the authors conclude that technological and managerial innovation is not related to the intensity of marketing innovation. At the same time, product innovation is interconnected and stimulates marketing innovation. Authors also argue that marketing innovations have a significant impact on the efficiency of the firm.

Thus, the first hypothesis can be formulated:

Hypothesis 1a: The intensity of product and technological innovation has a positive effect on the intensity of managerial innovation;

Hypothesis 1b: The intensity of managerial innovation leads to an increase in the intensity of organizational innovation.

[Colombo, Grilli, & Piva, 2006; Mol & Birkinshaw, 2009] also investigates the relationship between product, process, and organizational innovation, but the authors conclude that the relationships between different forms of innovation are not identical among companies. These relationships depend on the country of company origin, company size, and access to resources. But for all companies, the most successful was the combination of product and process innovations, and the least successful was the product, process and organizational innovations, which is associated with the high cost and labor intensity of this strategy.

In the works of other authors (for example, Garcia and Calantone, 2002), on the contrary, it is claimed that, despite the high costs, companies should focus on product, technological, marketing, managerial and organizational innovations simultaneously and implement different types of innovations in an integrated manner. This strategy allows companies to succeed and be effective.

At the same time, [Damanpour, F., Evan, W.M., 1984] indicate that companies engaged only in product innovation and neglecting organizational and managerial ones have lower productivity than companies implementing them. So technological and non-technological innovations are equally important to achieve high productivity.

Lin, C.Y., Chen, M.Y. (2007) pointing out the interconnectedness of innovations, come to a conclusion that it is organizational, and not technological, innovations that influence the company efficiency, expressed as annual sales.

However, [Chandler, G.N., Hanks, S.H., 1994] note a negative relationship between innovation and productivity, or do not confirm it at all.

Thus, the second hypothesis of the study can be formulated:

Hypothesis 2a: Product innovation is positively associated with indicators of sustainable development, expressed in:

(a) an increase in the share of sustainable products in total output; (b) reducing resource consumption; (c) development of qualified employees, expressed as the ratio of employee training costs to sales revenue;
Hypothesis 2b: Technological innovations are positively associated with indicators of sustainable development, expressed in: (a) an increase in the share of sustainable products in total output; (b) reducing resource consumption; (c) development of qualified employees, expressed as the ratio of employee training costs to sales revenue;
Hypothesis 2c: Management innovations are positively associated with indicators of sustainable development, expressed in: (a) an increase in the share of sustainable products in total output; (b) reducing resource consumption; (c) development of qualified employees, expressed as the ratio of employee training costs to sales revenue;
Hypothesis 2d: Organizational innovations are positively associated with indicators of sustainable development, expressed in: (a) an increase in the share of sustainable products in total output; (b) reducing resource consumption; (c) development of qualified employees, expressed as the ratio of employee training costs to sales revenue.

Research Methodology

Sample Description

Empirical testing of the hypotheses was carried out based on the analysis of data collected from January 2020 to April 2020.

For the analysis, 254 industrial enterprises with more than 250 employees were randomly selected. The questionnaire questions were preliminarily tested during in-depth interviews with representatives of 16 Russian industrial enterprises, in order to clarify the ambiguous interpretation of the questions. The collection of data was carried out by combining online questionnaires and telephone conversations, which made it possible to make the questionnaire questions clear.

Further, the selected 254 enterprises were sent an electronic mailout of questionnaires. The respondents were senior management and those in charge of innovation in companies. A total of 167 respondents from 123 companies answered.

The companies included in the sample belong to the industrial production, average revenue of the companies represented in the sample is 5280 million rubles. More than half of the companies surveyed have been operating in the market for more than 15 years, the age of the companies in the sample varies from 13 to 83 years and averages 34.

Research Variables

The indicators of company sustainable development, expressed by three indicators, were used as a dependent variable: (a) the share of sustainable products in the total output; (b) reducing resource consumption; (c) development of qualified employees, calculated as the ratio of employee training costs to sales revenue.

To measure product innovation, a three-question scale was used that assessed the ability of an industrial enterprise to create and commercialize new products and thus compete in the market.

Technological innovation was measured using four questions aimed at measuring the company's ability to use new technologies to optimize business processes, reduce costs, introduce new products and attract new customers.

Management innovation was measured using three questions aimed at assessing company's ability to innovate in management processes, including the ability to implement the concept of "open innovation" in building corporate innovation systems.

Organizational innovation is measured by questions about the company's ability to innovate in the company's organizational design, adapting to new markets and the production of new products (Table 1).

Table 1: Frequency of mentioning answers to questions about innovation activity by industrial enterprises

	Questions about company's innovation	Mentioning percentage
	Product innovation	
1	Company regularly introduces new products to the market	74,1
2	Company develops and creates new products	87,3
3	Company's new products comply with the principles of sustainable development	64,8
	Technological innovation	
1	Company uses existing technologies in a new way	34,8
2	Company implements new production technologies	86,9
3	Company aims at technological leadership in the market	76,9
4	New technologies reduce company's costs	47,9
	Management innovation	
1	Company has significantly expanded the number of partnerships to improve the effectiveness of research activities	19,7
2	Company employs third-party research teams for specific purposes using its own infrastructure	24,9
3	Company applies various forms of risk - investment, shares (reduces) the risks of "breakthrough" projects with co-innovators	12,8
	Organizational innovation	
1	Company has partners to achieve the goal of sustainable development	27,9
2	Company has its own R&D departments	69,4
3	Company is restructuring its organizational structure in order to better meet the conditions for development of new markets or release of new products that comply with the principles of sustainable development	38,1

As expected, the issues related to product and technological innovation are the most frequently mentioned. At the same time, when answering questions about managerial and organizational innovations, enterprises demonstrated a low ability to form partnerships, to implement the concept of open innovation in building corporate innovation systems.

The measurement of the main resulting indicators was based on three questions, for measuring each aspect of the company, laid down by the strategy of sustainable development: share of sustainable products in the total output; reducing resource consumption; development of qualified employees, calculated as the ratio of employee training costs to sales revenue.

The performance of industrial enterprises can vary significantly depending on the size, affiliation to a particular industry and the intensity of competition in the market, therefore, indicators of company size, a certain number of full-time employees, were used as control variables. To meet the assumption of normal distribution, the indicator was transformed using the natural logarithm. To account for differences in belonging, binary variables were used that indicate the belonging of an enterprise to a particular sector (1 - belongs; 0 - does not).

Competition intensity was measured as the combined market share of the three largest competitors in the company's largest market.

Data Analysis Procedure

To assess reliability, the Alpha - Cronbach coefficients were calculated, which corresponded to the recommended level - not less than 0.75 (Table 2). Further, a factor analysis was carried out using the principal component analysis (varimax) for 13 questions describing four types of innovations: product, technological, organizational and management. The analysis confirmed the presence of four factors with values above one in accordance with the Kaiser criterion.

In general, four types of innovations explain 73.6% of the variation in the answers to the questions (this result corresponds to the recommended value of at least 70% [27]) (Table 2). Factor analysis by the method of principal components (varimax) was used in a similar way for indicators of the enterprises' activity efficiency: increasing the

share of sustainable products in the total output; reduction in resource consumption; development of qualified employees, calculated as the ratio of employee training costs to sales revenue.

The analysis confirmed the named three types of sustainable development indicators, which generally described 72.6% variation in questions (Table 2).

Table 2: Factor analysis: questionnaire questions, load factors and reliability check (Alpha - Cronbach coefficient)

	Questions	Sum of squares of factor loads	Model1 for the factor "product innovations"	Model 2 for the factor "technological innovations "	Model 3 for the factor "organizational innovations "	Model 4 for the factor "management innovations "
	Innovation type					
1	*Product innovation (Cronbach's Alpha coefficient = 0.87)*					
1.1	Our company annually introduces products with new properties to the market	0,628	0,824	0,311	0,276	0,258
1.2	Our company develops and creates products that have no analogues on the market	0,534	0,728	0,254	0,196	0,221
1.3	New products of our company comply with the principles of sustainable development	0,664	0,733	0,329	0,247	0,253
2	*Technological innovation (Cronbach's Alpha coefficient = 0.82)*					
2.1	Our company uses existing technologies in a new way to create new products	0,718	0,221	0,741	0,346	0,258
2.2	Our company is constantly introducing new technologies	0,639	0,198	0,824	0,298	0,221
2.3	Our company's technologies can significantly save resources	0,784	0,237	0,889	0,307	0,253
2.4	New technologies introduced at our company can significantly reduce the cost of new products introduced	0,639	0,273	0,914	0,193	0,242
3	Management innovation (Cronbach's Alpha = 0.79)					
3.1	Our business has changed the role of R&D partners in order to improve performance	0,548	0,414	0,271	0,761	0,398
3.2	Our company has third-party research groups that engage in the implementation of specific sustainable development goals	0,671	0,363	0,259	0,695	0,401
3.3	Our company has created new methods of risk - investment, in order to share (reduce) the risks of "breakthrough" projects with co-innovators	0,528	0,423	0,164	0,727	0,314

4	*Organizational innovation (Cronbach's Alpha = 0.81)*

Values of the obtained factors of the types of innovation activity and the factors of sustainable development of industrial enterprises were used in the future in the regression analysis carried out using the mathematical model:

$$Y_i = \beta_0 + \beta_1 PROD_i + \beta_2 TECHN_i + \beta_3 ORG_i + \beta_4 UPR_i + \beta_5 COMP_i + \beta_6 SIZE + \beta_7 IND_i + \varepsilon_i$$
(1),

where $PROD_i$- product innovations; $TECHN_i$ - technological innovation; ORG_i- organizational innovation; UPR_i - management innovation; $COMP_i$ - the level of competition in the industry; SIZE is the size of the company; ; IND_i- industrial sector. Indicators of the competition level in the industry, company size, and the industry sector were introduced to monitor characteristics that can affect the sustainability of industrial companies.

Standardized and non-standardized coefficients were obtained using the maximum likelihood method, while standardized coefficients were used to determine the factor influence strength on the resulting indicator, and non-standardized ones were used to test the hypotheses of the study.

Research Results

Tables 3-5 show the results of the regression analysis that reflects the impact of various types of innovations (product, technological, organizational and managerial) on the industrial enterprises sustainable development indicators. In general, the results of the regression analysis confirmed the hypotheses of the study. Models based on equation (1) were able to explain 28% of the variation in the sustainable products share in total output; 17% - in reducing resource consumption; 24% - in employee development.

When analyzing the growth of sustainable products share (Table 3), it turned out that product innovations (β = 0.437; p <0.01), technological innovations (β = 0.192; p <0.05) and managerial innovations (β = 0.123; p <0.01) have the most significant positive influence. At the same time, organizational (β = 0.06; p <0.10) do not have a significant effect on this indicator. The variables of the industry sector (β = 0.061; p <0.05) and company size (β = 0.073; p <0.05) also do not affect this indicator. At the same time, the indicator of the competition level (β = 0.248; p <0.05) has a negative impact on the share of sustainable products. Thus, product, technological and managerial innovations are key factors in increasing the share of sustainable products in the studied sample.

Table 3: Influence of different types of innovations on the share of sustainable products in the total output

Independent indicators	Non-standardized ratios	Standardized ratios
Constanta - (β_0)	0,227 (0,117)	
Product innovation – ($PROD_i$)	0,437*** (0,094)	0,444***
Technological innovation – ($TECHN_i$)	0,192** (0,107)	0,198**
Organizational innovation - (ORG_i)	0,060* (0,047)	0,069*
Management innovation – (UPR_i)	0,123*** (0,019)	0,143***

Corrected R^2	0,28	
Number of observations	167	

** p < 0,10; ** p < 0,05; *** p < 0,01. Standard errors are given in parentheses.*

Analysis of the reduction in resource consumption by industrial enterprises (Table 4) showed that technological innovations (β = 0.274; p <0.05), product innovations (β = 0.192; p <0.05) and managerial innovations (β = 0.171 ; p <0.05) have the most influence. Organizational (β = 0.038; p <0.05) innovations do not affect the reduction of resource consumption by companies. The indicator of the competition level (β = 0.125; p <0.05) has a negative effect on the level of resource consumption, while the company size (β = 0.119; p <0.05), on the contrary, has a positive effect. The industrial production sector (β = 0.038; p <0.05) does not significantly affect the level of resource consumption.

Table 4: Impact of different types of innovations on the reduction of resource consumption by industrial enterprises

And finally, the analysis of personnel motivation and development (Table 5) showed that managerial innovations (β = 0.284; p <0.05), product innovations (β = 0.118; p <0.01), technological (β = 0.182; p <0.01) have a positive effect on the level of motivation and development of industrial companies staff. At the same time, organizational innovation (β = 0.065; p <0.10), the level of competition in the industry (β = 0.063; p <0.05), the industrial production sector (β = 0.071; p <0.05) and company size (β = 0.055; p <0.05) do not have a significant impact on this indicator of sustainable development of industrial enterprises.

Hypothesis Testing Results

To test the first hypothesis regarding the relationship between different types of innovations, were calculated Spearman's nonparametric correlation coefficients; to recognize the relationship between individual indicators, the value of this coefficient should exceed 0.5.

Correlation analysis showed that product innovations are associated with changes in existing technologies (ρs = 0.62) and additional management innovations associated with the search for partners, consumers, suppliers, etc. (ρs = 0.54). Technological innovation is also correlated with managerial innovation (ρs = 0.59), as it is associated with customer solutions, the choice of technological solutions and their suppliers, and the role of partners in research and development. In general, hypothesis 1a is confirmed, the intensity of product and technological innovations has a positive effect on the intensity of managerial innovations.

Interviews with representatives of Russian industrial enterprises also showed an associative relationship (associations) between managerial and organizational innovations (ρs = 0.57) and provided a rationale for confirming hypothesis 1b that the intensity of managerial innovation leads to an increase in the intensity of organizational innovation.

Testing the second hypothesis describing the impact of various types of innovations on the industrial enterprises sustainable development is fully confirmed for product innovations (hypothesis 2a) - they have a positive effect both on the industrial enterprises sustainable products share ($\beta = 0.444$; $p < 0.01$) and on the reduction resource consumption ($\beta = 0.198$; $p < 0.01$) and employee motivation and development ($\beta = 0.324$; $p < 0.01$).

The impact of technological innovation (hypothesis 2b) is also confirmed: technological innovation has a significant impact on the share of sustainable products ($\beta = 0.198$; $p < 0.05$), resource reduction ($\beta = 0.183$; $p < 0.05$) and staff motivation and development ($\beta = 0.288$; $p < 0.05$).

Management innovations (hypothesis 2c) also have a significant impact on the share of sustainable products ($\beta = 0.143$; $p < 0.01$), reduction in resource consumption ($\beta = 0.139$; $p < 0.01$) and staff motivation and development ($\beta = 0.179$; $p < 0.01$).

Finally, the hypothesis regarding the impact of organizational innovation (hypothesis 2d) has not been confirmed. Organizational innovations do not have a significant impact on any of the industrial enterprise sustainable development indicators.

Thus, we have shown the significance of the constructed model describing the influence of various types of innovations and confirmed the influence of various types of innovations in industrial enterprises on the sustainable development indicators, expressed by indicators of an increase in the sustainable products share in the total output; reduction in resource consumption; motivation and development of qualified employees.

Conclusion

The work carried out a comprehensive multifactorial study of the impact of various types of innovations on the industrial enterprises sustainable development indicators.

Within the framework of this study, four types of innovative activities of industrial enterprises were identified: product, technological, organizational and managerial, which were measured as a result of a survey of a sample of 123 enterprises (167 respondents) and used to analyze sustainable development. The survey confirmed that the majority of the surveyed companies associate the improvement in the sustainable development level with product and technological innovations, while organizational and management innovations are significantly underestimated by the respondents. At the same time, within the framework of product innovations, respondents more often noted the importance of developing, creating and launching new products on the market than describing them as a product that meets the sustainable development principles. The respondents most often associated technological innovations with the introduction of new production technologies and the achievement of technological leadership in the market. The problem of reducing costs and using existing technologies in a new way turned out to be irrelevant for the majority of respondents.

Also, low scores were obtained when answering questions about the impact of managerial and organizational innovation.

The results of the quantitative analysis confirmed most of the hypotheses put forward. Thus, the first hypothesis about the relationship of innovations was confirmed, it was found that product and technological innovations are positively interconnected with managerial innovations, and the intensity of managerial innovations leads to organizational innovations. We also succeeded in identifying separate profiles of different types of innovations of the companies in the sample. Thus, the share of sustainable products of industrial enterprises is more influenced by product, technological and managerial innovations, as well as by the reduction of consumed resources, and the staff motivation and development. The influence of product and technological innovations on staff development is interesting, which can probably be explained by the influence of spillover effects of knowledge.

When analyzing the impact of control variables, only the negative impact of industry competition on the development of sustainable products was significant.

Thus, depending on the goals that an industrial enterprise sets for itself, it is possible to combine investments in certain types of innovative activities and thereby achieve the goals set in the field of sustainable development. Understanding the complex nature of innovation will enable businesses to build long-term, non-replicable competitive advantages.

Laundry Processes and their Impact on Sustainability in the Aspect of Consumers Behaviors

Renata SALERNO-KOCHAN

Department of Non-food Product Quality and Safety, Institute of Quality Science and Product Management, Cracow University of Economics, Cracow, Poland, e-mail: salernor@uek.krakow.pl

Abstract

Laundry processes are treatments inherent in the use phase of textiles. The way they are conducted by consumers, including the type of equipment they use, washing, drying and ironing frequency, the choice of washing temperature, and size of load have a significant impact on the amount of carbon footprint associated with energy and water consumption. Taking this into account, the research purpose was to find out consumer habits and practices regarding laundry processes as an important phase in the life cycle of clothing products that affect the assessment of their environmental impact. The article deals with the problem regarding the level of carbon dioxide emissions in individual washing processes depending on the composition of clothing and the type and frequency of care treatments. Based on the performed surveys among Polish consumers, it was found that their approach to these processes is rational. Their households are equipped with high energy class washing machines, washing is carried out with moderate frequency, trying to make the washing drum as full as possible, they apply optimal bath temperatures and make little use of clothes dryers. Their attitudes significantly affect water and electricity savings.

Keywords: consumer behavior, clothing, laundry processes, sustainable development

Introduction

The population growth, the improvement of living conditions, as well as the development of materials and technologies, caused a high increase in consumer goods production and consumption. The consequence of this is an excessive carbon dioxide emission and environmental imbalance manifested in ecosystem pollution, waste generation, and climate change. The textile and clothing industries contribute significantly to these negative changes. They are classified among most polluting industries in the world (Choudhury 2014, Athalye 2012). In 2015, they emitted 1.2 billion tons of greenhouse gases (as CO_2 emission) as a result of energy use (A New Textiles Economy… 2017). Apart from high energy consumption, water usage, estimated at 79 billion cubic meters annually, and waste generation, amounting to 92 million tons, is a huge problem.

Research indicates that not only manufacturing processes of these industries contribute to environmental degradation (Muthu 2015). For a large share of this degradation the post-production sphere, connected with consumer behavior regarding clothing purchasing, their usage, maintaining and waste disposal practices, is responsible. Most of the available literature sources focus on consumer purchasing behavior while little research takes into account their habits during laundering processes. Especially such parameters as:

- washing temperatures, class of washing machines, washing cycles and washing frequencies, kind and amount of detergent used;
- drying timings, temperatures, frequencies, drying methods;
- ironing timings and temperatures,

were found to be the most important, requiring special attention concerning the environmental impact of clothes.

As sustainability is a topic of high importance nowadays and the washing, drying and ironing processes are an important phase in the life cycle of clothing products that affect the assessment of their environmental impact, therefore, the purpose of the article was to present laundry processes in terms of their impact on greenhouse gas emissions, taking into account various parameters of carrying out of them (e.g. temperature, frequency) and to show how they can be influenced by consumer habits and practices.

Background of the study

According to Muthu (2015) the harmfulness of the post-production sphere of the clothing industry, measured by the amount of greenhouse gas emitted, is largely due to clothing care processes that are highly energy- and water-consuming. For example, the energy consumption for these processes is estimated at around 24.2 TWh per year (Pakula and Stamminger 2010). Bertoldi, Hirl and Labanca (2012) report that these processes consume about 7.2% of the electricity used by households in Europe.

Ironing is by far the most cumbersome process of garment care. It emits from 510 to even 1070 g of CO2 for every hour of ironing (*The Guardian* 2019). Its share in the carbon footprint, taking into account the entire life cycle of a given item of clothing, can reach up to 17% (Fig 1). It absorbs significant amounts of energy, especially in terms of linen, cotton and viscose products, compared to products made of synthetic fibers or wool.

The process of clothes laundering comes in second in terms of carbon dioxide emissions, with approx. 0.21 kWh per 1 kg of laundry load washed at 40°C. The use of 60°C wash setting instead of 40°C may result in an increase in the carbon footprint by up to 45%, while lowering the temperature from 40°C to 30°C may contribute to a reduction of the carbon footprint by even 40% (Jungmitchel 2010). According to Josephy et al. (2013), washing at max. 20°C temperatures uses even 70% less electricity compared to a 60°C cycle. The environmental burden of this process is also associated with the use of water and detergents.

Drying clothes in the washing machine requires up to 3-4 times more energy than the laundering process. Consequently, the use of both of these processes can lead to the consumption of much more than 4 kWh per washing cycle (Table 1). Drying clothes in tumble dryers is therefore an economically unprofitable practice; and most importantly, it is highly environmentally unfavorable (Apparel Industry…2009).

Fig. 1: The impact of clothing production and usage on environment (CO_2 emission)

Table 1: Energy consumption during washing and drying processes

	Washing machine	Dryer
Mass per loading	3.65 kg	4.5 kg
Use of loading volume (average)	60%	75%
Use per wash cycle	100%	17%
Average energy consumption	0.8 kWh	3.33 kWh

Source: Jungchmitel N. (2010), The Carbon Footprint of Textiles, http://www.ci-romero.de/fileadmin/media/informierenthemen/gruene_mode/Jungmichel._Systain.pdf.

The amount of CO_2 emissions depends on the frequency of garment care processes, especially of drying and ironing. According to Jungmitchel (2010), undertaking these activities after each washing cycle would increase the carbon footprint by up to 300%. Yet, it should be noted that the amount of carbon dioxide emissions resulting from the washing processes strongly depends on the type of raw material from which the item of clothing is made. In this respect, synthetic fabrics perform better. It is relatively easier to remove dirt from them and it can be achieved at lower temperatures. They also dry much faster compared to cotton. On the other hand, studies have shown that one load of washing of polyester clothes (as well as nylon and acrylic) can issue up to 700,000 microfibers that release toxins into the environment, and thus can enter the food chain of humans and other organisms (Choudhury 2015).

With the production systems currently in use, the amount of microfiber in the oceans can increase up to 22 million tons by 2050.

The degree of the negative impact of clothing care processes on the environment depends to a large extent on consumer practices. Therefore, the research was undertaken to learn more about consumer habits concerning washing processes.

Method Description and Characteristic of Respondents

Taking into account performed literature study some research questions were defined. They related to the types of equipment they use, regarding energy efficiency rating, the frequency of washing, ironing, drying treatments they perform, the type and amount of detergents, the temperature of washing and ironing they use, etc. that have a significant impact on the quantity of carbon footprint they create.

The research goal was to find out Polish consumer habits and practices concerning washing processes and to compare with attitudes towards clothing maintenance of other nationalities.

The data for this research were gathered in 2019 through an online enquiry posted on Google Docs. A targeted sample selection was used. A self-administered online questionnaire has been distributed to household representatives through social networks. The questionnaire contained single and multiple-choice questions, as well as scaled questions. The use of an ordinal scale (a quasi-quantitative) was connected with the possibility to utilize methods developed for numerical data, such as the arithmetic mean and standard deviation (Medhi, 1992; Zeliaś, 2000).

The survey questions concerned consumer attitudes towards clothing maintenance, including washing, ironing or drying processes. The survey was attended by 150 respondents, 63% of whom were women and 37% were men. The age of respondents was divided into three compartments – 18-25 years; 26-35 years and over 36 years. The number of respondents by age and gender is set out in Table 2.

Table 2: Structure of respondents

	Female	**%**	**Male**	**%**	**Sum**	**%**

Results and Discussion

From among the 150 subjects who took part in the survey, 133 respondents maintain their clothes on their own, including 131 of them most often using a washing machine, and 2 individuals declaring manual washing. None of the respondents declared that they regularly use dry cleaning or self-service laundries.

The research results show that 77% of respondents have an energy class A+ washing machine or higher, and 22% own class A washing machines. This is a very positive finding, indicating that consumers consciously choose such household appliances, and thus contribute to lower electricity and water consumption. Washing machines of energy class B and lower attract very little interest with only 1% of respondents declaring the use of them. Almost 81% of respondents admitted that they do not have automatic dryers in their households, which confirms a persistently low interest in these appliances among Polish consumers compared to consumers from other countries. As shown by research carried out in 2016 (Gwozdz, Steensen Nielsen and Müller, 2017), only about 12% of households in Poland were equipped with tumble dryers or in 2018 even only about 3% (GUS 2019), while in Germany and Sweden these figures were at 20% and in the USA at 80%. In turn, the findings of the present study suggest that among the individuals who have such appliances in their houses, only 4% use them regularly, 8% often, 1% sometimes and 6% rarely. The study also shows (Fig 2) that in the case of the frequency of washing, the respondents most often perform such chores once or twice a week (about 35%). Laundry done 3 to 5 times a week was indicated by 24% of the subjects surveyed, whereas only few of the respondents declared that they do the washing daily (2.6%) or less often than once a week (4%).

Fig. 2: The number of responses regarding the frequency of clothing washing performed by Polish consumers per week

The results of this study have indicated similar behaviors in this area of household activities among Polish and Finnish consumers. Research by Miilunpalo and Räisänen (2018) shows that more than 95% of Finnish residents use washing machines, more than half of them wash their clothes several times a week, fewer than 13% daily, and a third - once a week. Another survey question concerned the washing process itself, including drum fullness and the selection of wash and rinse cycles. The research results have shown that respondents make sure that the washing machine drum is full or three-quarters full - around 80% of respondents make such declarations. As many as 8% of those surveyed, fill the washing machine drum half, and the rest, i.e. 12%, do the laundry with smaller loads. None of the respondents admitted that they wash individual items of clothing. Finnish consumers, on the other hand, declare that they more often carry out the washing process without a full drum load (43% of respondents - almost always, 37% - often). Only 23% admit that their washing machine drum is full every time, and 26% - often (Miilunpalo and Räisänen 2018). This is also true for German consumers. The research conducted in 2014 revealed that in most cases they do not completely fill the drum, which, according to the author of the study, significantly increases the number of washing cycles, and thus translates into greater energy and water consumption (Kruschwitz et al. 2014).

The results of this study suggest that respondents generally choose such wash settings which are dedicated to the particular type of fiber from which the clothes are made, and so - 32% of respondents indicated the choice of the washing cycle for cotton products, 19% - for washing synthetic materials, while the least frequently chosen setting (3% of responses) is the program for washing wool. The ECO washing cycle, indicated by only 24% of respondents, is not an obvious choice for washing machine users. But this result shows an upward trend compared to the results presented by Alborzi et al (2017), who indicated 17% share of the ECO program in the total number of washing programs declared by the respondents. The setting selected by Polish consumers most often (53% of responses) is a short washing cycle. However, it is worth noting that among them, 33% of such indications came from individuals with higher education. Almost a third of respondents (32%) most often choose their own washing parameters without consulting the manual, of which 22% of the subjects had a higher education. Over 75% of respondents most often

choose temperatures ranging from 30°C to 40°C, 18% - from 50°C to 60°C, and 5% - up to 30°C. For comparison purposes, according to research conducted among Finnish consumers, most subjects wash their clothes at 60°C (45% of respondents), and 15% at 40°C. Some of the respondents also wash their clothes at higher temperatures, up to 90°C. The study has shown that many Finnish consumers do not believe in the information on the labels and often wash their clothes at higher temperatures than recommended. These people tend to believe that the washing instructions provided by the manufacturers are too cautious, or that temperatures below 60°C do not fully remove dirt, such as sweat or fat (Alborzi et al 2017, Miilunpalo and Räisänen 2018).

The next item in the questionnaire was designed to check consumer practices in relation to ironing. The average percentages of respondents' answers to this question, taking into account their gender, are presented in Fig 3. On an ordinal scale - from 5 to 1, where 5 stands for “always” and 1 – “never”, respondents defined their typical behavior.

Fig. 3: The respondents' habits with respect to the ironing of clothes

Based on the obtained responses, both male and female subjects most often iron the clothes before putting them on. This practice obtained the highest average rating among the respondents (3.27 pts). The statement "I iron clothes after each wash" came in second, with an average answer rating of 2.56 points. Such approach to ironing is more common among female subjects (2.66 pts) rather than male ones (2.33 pts). Standard deviation values were at the level of 1.5 points, suggesting a large dispersion of responses in relation to this practice. In the third place, with an average rating of 2.35 points, respondents indicated the statement "I do not iron very often because I try to buy clothes that do not require ironing" - in this case the share among the responses of female and male subjects was very similar. A large difference between the responses among men and women was noted in relation to the statement "I do not iron clothes at all". Such approach is much more common among men (2.63 pts) compared to women (1.95 pts). The results of respondents' answers, at the level of 1.15 points, also indicate a very seldom use of dry cleaning.

Conclusions

Considering theoretical and empirical studies on the impact of washing, drying, and ironing on the environment and the results of own research, it can be stated that Polish consumers exhibit a rational approach to garment care methods. As shown by the respondents’ declarations, consumers generally do their laundry at home (99% of respondents), performing one or two washing cycles per week (68% of respondents), using high energy class washing machines (99% of respondents declare having a min. A energy class washing machine, and 77% - a min. A+). Fewer than 20% of respondents declare that they have automatic dryers, but only 4% use them regularly. Almost 80% declare full drum loading before starting the washing machine, 75% declare washing at 30-40°C, and approx. 53% of respondents use short washing cycles. Unfortunately, ECO wash settings, which are selected by 24% of respondents, boast little popularity. It was also found that individuals with higher education normally use less energy and water-consuming settings. Positive behaviors have been found with regard to ironing as well and are related to the respondents' declarations that they perform this activity just before putting on their clothes (3.27 pts on a 5-point scale). On the other hand, the declaration of ironing after each wash (average rating 2.66 pts), as well as a low rating (2.35 pts) regarding the attitudes aimed at eliminating the ironing process, especially among women, indicate that there are still some areas of possible habit change that may contribute to the reduction of energy consumption.

Emprendimiento E Innovación En Las Universidades

Sussy BAYONA-ORÉ

Universidad Autónoma del Perú, Lima, Perú
Sbayona@hotmail.com

Abstract

The days of COVID-19 have exposed the limitations of many small businesses to reinvent their businesses, in many cases the breadwinner. Innovation, research and entrepreneurship are all related concepts. The survival of many businesses will involve a range of skills and knowledge on the part of the entrepreneur. Universities are educational centers in which future entrepreneurs are formed and there resides the importance of providing courses related to the formation of companies. This article presents the presence of entrepreneurship, innovation, technology and research in the vision and mission that universities and ICT-related careers have defined. The results show that there is a low percentage of the presence of the terms Innovation, Entrepreneurship, Technology in the Vision and Mission of the Universities. Few ICT-related careers have incorporated innovation entrepreneurship courses. The careers that have incorporated the courses, these are located in the different cycles of the career.

Keywords: entrepreneurship, businesses, innovation, universities.

Introducción

La propagación del SARCS-CoV-2 ha impactado a nivel global y local la economía en el contento mundial, regional y local. El distanciamiento necesario para evitar la propagación del virus y las oleadas ha traído consigo el cierre de negocios. Muchos emprendedores se han visto en la necesidad de reinventar el modelo de negocio bajo el cual operaba su empresa, haciendo uso de la tecnología e innovando para ofrecer nuevos productos y servicios. Con más de 86.3 millones de casos y más de 1.8 millones de muertos en todo el mundo (RTVE, 2021), los países se han visto obligados a tomar medidas cada vez más restrictivas que al inicio de la pandemia.

Por ello, la importancia de promover el emprendimiento, en especial en épocas de crisis (Martínez & Bañon, 2020), como es el caso del confinamiento y distanciamiento social, originada por la COVID-19, considerando que el emprendimiento esta relacionado con la creación de empleo y la introducción de nuevos productos y servicios. El emprendimiento está relacionado con un conjunto de características individuales, tales como tener autoconfianza, ser perseverante, tener coraje, ser creativo y asertivo (Martínez & Bañon, 2020), características que facilitan el emprendimiento. Además de propiciar la investigación en emprendimiento (Muñoz Palacios, 2017). Al respecto Robayo (2016) sostiene que hay una escasez de investigaciones que exploran la creatividad y la innovación.

Uno de los retos del emprendimiento es la digitalización para impulsar el desarrollo de nuevos procesos, productos y servicios. La digitalización ha hecho posible proveer de productos y servicios de manera diferente en un periodo de confinamiento vivido (Haeffele et al., 2020). La digitalización está relacionada con los programas de formación relacionadas con Tecnologías de Información y Comunicaciones (TIC) que ofrecen las universidades. Por un lado, la formación universitaria determinan positivamente el grado en el que las empresas han utilizado las TIC (Martínez & Bañon, 2020). Por otro lado, desarrollar emprendedores calificados y profesionales capaces de generar empleos es una función de las universidades. Al respecto, Saldarriaga & Guzmán (2018) afirman que "la mayoría de las universidades tienen en cuenta guías o estrategias para la formación de emprendedores", pero pocas han desarrollado modelos propios para la enseñanza del emprendimiento y la generación de ideas de negocio.

Implementar cursos de emprendimiento, en el proceso formativo de los universitarios, tienen como propósito promover que los estudiantes y futuros egresados tengan los conocimientos y las habilidades para ser emprendedores y puedan formar sus propias empresas. En especial, por que la gente joven son especialmente capaces de producir grandes ideas, tanto en investigación científica, invención o emprendimiento (Jones et al.,

Cite this Article as: Sussy BAYONA-ORÉ "Emprendimiento E Innovación En Las Universidades" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

2014, Azoulay et al., 2020). Por un lado, los emprendedores jóvenes son más propensos a iniciar un negocio motivados por una oportunidad al inicio de su carrera que es menos fuerte en la mediana edad (Molina, 2020). Por otro lado, la educación está relacionada positivamente con las motivaciones de oportunidades y desafíos y los emprendedores con un alto nivel que dependiendo de las características individuales una persona educación universitaria pueda decidir por un trabajo asalariado (Molina, 2020).

De lo anterior, el entorno universitario puede fortalecer el nivel de emprendurismo de los estudiantes a través de cursos de formación y/o talleres. Proveer personas con habilidades para el emprendimiento puede ser una contribución relevante a la sociedad de parte de las universidades (Audretsch 2014). La educación para el emprendimiento a menudo mejora la actitud de los estudiantes hacia el emprendimiento (Xingjian, Liu andJian, 2019). Algunas universidades buscan generar programas para apoyarlos con recursos para poner en marcha sus ideas de negocio (Saldarriaga & Guzmán, 2018). En un estudio realizado sobre la intención emprendedora que mostraban los estudiantes que llevaron un curso de emprendimiento, se concluyó que estaban más interesados en emprender un negocio a diferencia de los que no llevaron el curso (Bui et al., 2020).

En este artículo se presenta un estudio sobre la presencia de términos relacionados al emprendimiento, la innovación y la tecnología en la visión, misión y valores de las universidades licenciadas, que cuentan con carreras de Tecnologías de Información y Comunicaciones, así como los cursos que se ofrecen para propiciar el emprendimiento de los universitarios.

Marco Teórico

Emprendimiento

El concepto de emprendimiento difiere según los autores. Peter Drucker definió “entrepreneurship” como la actividad creativa que implica tomar ventaja de los recursos disponibles para crear en riqueza de una manera nueva (Drucker, 1985). Otra definición de emprendimiento se refiere a la capacidad de crear a partir de cero un proyecto, una iniciativa o un negocio (OBS, 2019). El emprendimiento puede definirse como el proceso que “requiere de creatividad e innovación para crear y aprovechar oportunidades para aportar valor a la sociedad” (Bui,2020). A la persona que organiza u opera un negocio se denomina emprendedor y la intención de emprendimiento indica la tendencia de una persona para iniciar un negocio en el futuro. El emprendimiento es un factor clave en la formación de empresas y la innovación es una palabra que está presente en su definición.

Universidades y el Emprendimiento

La universidad juega un rol importante en la creación de una sociedad emprendedora y una cultura empresarial. Según Etzkowitz (2007) en el modelo de la triple hélice las universidades juegan un rol importante en la generación de conocimiento y tecnologías que pueden tener aplicación en la industria. A nivel mundial los programas de formación sobre espíritu empresarial siguen en crecimiento. Estos programas tienen el propósito de dotar de conocimientos y desarrollar las habilidades de los participantes para iniciar y mantener empresas (Kadir et al., 2012). Diversas universidades en su programas de estudios de las diferentes carreras implementan programas educativos orientados a la formación de futuros emprendedores. Aunque pueda existir una diferencia de la estructura, de los contenidos, de la metodología y las técnicas educativas son creadas con un propósito y temas similares, como es el estimular el desarrollo económico del entorno (Peterka et al., 2015).

En el proceso de transformación digital que se vive, las especialidades relacionadas a TIC juegan un importante rol en la formación de emprendedores que aporten valor y apoyen el proceso de digitalización para impulsar el desarrollo de nuevos productos, servicios y/o procesos. Las TIC permiten procesar administrar y compartir la información haciendo uso de diferentes soportes tecnológicos (Colegio de Ciencias y Humanidades, 2019). La Tecnología ha permitido crear nuevos productos y servicios (Publissoft, 2019). De lo expuesto, se resalta la importancia de las carreras universitarias relacionadas con TIC por su importancia para el desarrollo tecnológico. Es así, que en diferentes universidades se han realizado modificaciones en las metodologías de enseñanza o se ha mejorado las mallas curriculares con un enfoque en la formación de personas emprendedoras.

Fundamentos de Administración

Un elemento principal del proceso administrativo es la planeación, fase en la que se establece las bases de toda institución. En esta fase se detalla la misión, visión y los valores de la organización, los cuales constituyen el proceso de planeamiento estratégico. La misión y visión es la razón de ser de las empresas y la cual debe estar fundamentada por valores y principios (Louffat, 2010). La visión es prolongación hacia el futuro de una misión, el

cual se basa en seguir el desarrollo institucional (p. 16). Por otro lado, los valores institucionales son los principios, ideas y creencias que respaldan a la misión, dándole un perfil a la cultura organizacional.

Metodología

Este estudio es de tipo descriptivo, cuantitativo y transversal, que se realiza en el sector educativo. La población estuvo constituida por las universidades peruanas que han sido licenciadas por la Superintendencia Nacional de Educación Superior Universitaria – SUNEDU (SUNEDU, 2020), que ofrecen carreras relacionadas con las TIC, del nivel de pregrado. La muestra estuvo constituida por las carreras relacionadas a TIC con paginas web disponibles. Se ubicaron las paginas oficiales de la universidades, para extraer la información relacionada a visión, misión, valores, y el perfil del egresado tanto a nivel de universidades y a nivel de las carreras. Así mismo se identificaron aquellas especialidades que ofrecían cursos relacionados con Innovación, emprendimiento, formación de empresas. La información recolectada fue registrada en hojas electrónicas. Datos como la visión misión, valores y la presencia de las variables de estudio: innovación, emprendimiento, tecnología y creatividad. Así mismo se identificaron las sumillas de los cursos que formaban parte de la malla curricular de las carreras

Resultados

Universidades y las Carreras Relacionadas a TIC

De un total de 92 universidades licenciadas por la SUNEDU, el 74% (68) cuentan con carreras relacionadas a TIC. Del total de las universidades que cuentan con carreras relacionadas a TIC, el 54% son privadas y el 54% son públicas. La carrera universitaria que ofrecen las universidades es Ingeniería de Sistemas. Le siguen en orden de frecuencia las carreras de Ingeniería de Sistemas e Informática, Ingeniería Informática, Ciencias de la computación, Ingeniería de Software e Ingeniería de Sistemas y Computación.

Emprendimiento Innovación y Creatividad

La visión, misión y valores de las universidades forman parte del plan estratégico de las universidades. Las carreras alinean su plan estratégico a los lineamiento estratégicos que define la Universidad. En este estudio, la visión misión y valores de las universidades y de las carreras relacionadas con TIC fueron analizadas. Este análisis se realizó con el propósito de identificar si habían sido considerados aspectos relacionados a la Innovación, Emprendimiento, Creatividad y Tecnología. Se identificaron dichos términos en la misión, en la visión y en los valores.

En la Visión, los términos que más utilizados son Desarrollo, Académica, Social, Calidad, País entre otros (véase Figura 1 A). Mientras que en la Misión de las universidades los términos más utilizados son Desarrollo, Formación, Responsabilidad social, Investigación, Científica, Profesionales entre otros (véase Figura 1 B). Del análisis de los términos más utilizados en la Visión establecida por las carreras TIC, los más frecuentes fueron Desarrollo, Profesional, Internacional, Formación, Calidad, País entre otros (véase Figura 2 A).

A) B)

Fig. 1: Nube de palabras de la Visión (A) y la Misión (B)de las universidades

Mientras que en la Misión establecidas por las carreras TIC, los términos más utilizados fueron Desarrollo, Sistemas, Ingeniería, Investigación, Tecnología, Formación, Sociedad entre otros. Así mismo, se aprecia la presencia de términos Innovación e Innovador (véase Figura 2 B).

A) B)

Fig. 2: Nube de palabras de la Misión (A) y la Visión de las especialidades relacionadas con TIC (B)

Los resultados muestran que en la visión y misión de las universidades, así como de las carreras relacionadas con TIC, no se realiza una enunciando declarativo sobre las actividades de emprendimiento. En la misión de las carreras TIC si están presentes términos relacionados con Investigación, Innovación, Tecnología e Ingeniería. Se aprecia alineamiento en la definición de la misión de las Universidades y la misión de las carreras relacionadas a TIC, en cuanto a la Investigación.

Cursos relacionados al emprendimiento que ofrecen las universidades

Para conocer como las carreras relacionadas a TIC de las diversas universidades promueven la formación de futuros emprendedores se ubicaron las mallas curriculares. En las mallas curriculares se identificaron los cursos que estaban relacionados con la formación de empresas, que se aproximen al menos a las dimensiones de emprendimiento e innovación. Los resultados muestran que un 63% de las universidades tienen cursos vinculados a Innovación Tecnología y Emprendimiento (ITE) un 10% no los tiene y un 27% no estaban disponibles en sus páginas web.

En la Tabla 2 se presenta un resumen de los nombres de los cursos que ofrecen las especialidades TI (que se presentan con una frecuencia mayor a 2) que estaban disponibles en las páginas web. Los cursos relacionados con el emprendimiento y/o formación de empresas cuentan con diferentes denominaciones.

Tabla 2: Cursos que ofrecen las diferentes especialidades

Nro 1	Cursos	Cantidad	Sumilla
1	Emprendimiento de negocios sostenibles	3	Si
2	Gestión Empresarial	3	No
3	Innovación y Emprendimiento	3	No
4	Administración para los Negocios	2	No
5	Emprendedurismo	2	No
6	Emprendimiento e Innovación	2	No
8	Seminario de Tecnología e Innovación	2	No

La formación de emprendimientos empresariales auspiciados por las universidades en los programas vinculados a las TIC es insuficiente. Si bien se muestra la presencia de cursos orientados al emprendimiento y/o formación de empresas, que ofrecen las carreras relacionadas con TIC se hace necesario que las carreras que no los ofrecen, lo

incorporen en sus mallas curriculares. De tal forma que se formen profesionales capaces de crear empresa y generar empleo.

En la Figura 3 se presenta una nube de palabras de los cursos que se dictan en las diferentes carreras identificadas. Se observa que en la mayoría de los cursos están orientados al emprendimiento. El emprendimiento esta relacionado con la Innovación y la creatividad. La creatividad es una característica deseada de los emprendedores. Así mismo, la tecnología está presente. En los diferentes cursos el Plan de negocio es un aspecto importante que debe ser considerado.

.

Fig. 3: Nube de palabras con la lista de los cursos que ofrecen las universidades con carreras relacionadas a TIC

De las carreras que ofrecen los cursos sobre emprendimiento, se observa que estos están distribuidos en los diferentes ciclos. Al analizar la información recolectada se observa que la mayoría de los cursos están distribuidos entre el octavo ciclo con 29%, en el sexto ciclo un 16%, el quinto ciclo con un 14% y el noveno ciclo con un 13%. En general los tópicos de los cursos de formación están orientados a Emprendimiento, los modelos de emprendimiento, la innovación, las características del emprendedor, el innovador, plan de negocio, proyecto, tecnología, valor, empresas entre otros.

La formación de emprendedores se puede analizar desde el punto de vista académico, analizando los cursos que se ofrecen y las prácticas con el mercado. Se ve un interés creciente en la formación de emprendedores. Razón por lo que las universidades deben incorporar en las diferentes carreras, cursos orientados a dotar de conocimientos y desarrollar las habilidades para el emprendimiento. La Tecnología e Innovación juegan un papel importante para contar con productos y/o servicios que agregan valor diferenciado a los clientes.

Conclusiones

En este estudio se analizó la visión, misión y valores que fueron definidas por las universidades y las respectivas carreras relacionadas con TIC. Los términos más frecuentes que han sido utilizados son Investigación, Innovación, Tecnología e Ingeniería. En cuanto a la formación en emprendimiento en las universidades y las carreras relacionadas con TIC se observa que se ofrecen diversos cursos sobre emprendimiento, formación de empresas, administración para los negocios, innovación y emprendimiento entre otros. Los cursos que se ofrecen tienen diferentes denominaciones, sin embargo están presentes aspectos relacionados con el Emprendimiento, Innovación, Investigación, Tecnología y formación.

Se observa un porcentaje bajo de universidades con carreras relacionadas a TIC, cuyas mallas curriculares están disponibles en las páginas web institucionales. No todas las carreras relacionadas a TIC, han incorporado en sus mallas curriculares cursos sobre emprendimiento. Es importante que las diferentes carreras incorporen cursos de innovación y emprendimiento para dotar de conocimientos y desarrollar las habilidades a los estudiantes hacia el emprendimiento.

Keywords*:* thermoactive scanning, IT in medicine, stress, motor activities

Introduction

The relationship between stress and human functioning in an organization has been the subject of research all over the world for years. Most of the studies in this area are focused on medical and psychological aspects. In the era of the development of ICT support tools, it is possible to implement the thermoactive scanning instruments in the methodology of assessing the relationship of stress factors (stressors) with the distribution of selected neurotransmitters. A derivative of this type of research is the ability to assess management / command styles, which is extremely useful in assessing the suitability of employees for positions held in the organization.

Stress as a dynamic adaptive relationship

Stress as a type of mental tension is defined in psychology as a dynamic adaptive relations between the possibilities of an individual and the requirements of the situation (stressor, aversive stimulus), characterized by a mental and physical imbalance. In medical terminology, stress is a disruption of homeostasis caused by a physical or psychological factor. Factors that cause stress can be mental, physiological, anatomical or physical. The concept of stress was introduced to use by H. H. Selye, who was the first to hypothesize that a number of somatic diseases are the result of human inability to cope with stress. This phenomenon is called the so-called failure general adaptation syndrome. There are 3 types of stress in typology [1]:

Stress as a stimulus - situations in our environment that have the natural ability to cause tension and strong emotions. The theories associated with this type of definition include: the theory of G.R. Elliott and C. Eisdorfer, the concept of I.L. Janis and the concept of life changes by T. Holmes and R. Rahe.

Stress as a reaction - both physiological and psychological being a response to the effects of stressors (stress-inducing situations). The theories associated with this type of definition include: W. Cannon's homeostatic theory or Seley's concept [2].

Stress as a process or transaction - a relations between an individual and the environment: R. Lazarus' transactional model, A. Antonovsky's concept, S.E. Hobfoll, T. Tomaszewski's concept of difficult situations, J. Reykowski's regulatory and information theory of stress.

Fig. 1 : Stimulating (beneficial) and negative impact of stress on an individual
Source: personal study based on: I. Heszen, H. Sęk (2007), Psychology of health, Warsaw: PWN

There are also three types of stress reactions [3]: distress is the body's reaction to a threat, difficulty or inability to achieve important goals and tasks of a person, it occurs when a stimulus is triggered, i.e. a stressor; eustress is stress that positively mobilizes to action and neustress as a stimulus neutral in action for a given person, although for others it can be eustressive or distressing. Managing stress is cognitive and behavioral efforts to manage, reduce, or tolerate external or internal demands. Fig. 1 shows the stimulating (beneficial) and negative impact of stress on an individual (person).

Scanning Thermoregulatory Diagnostics as a tool of IEMSS

Scanning Thermoregulatory Diagnostics STRD is an examination that uses the variability of infrared radiation. It is standardized and can be an indicator of the overall activity of the nervous system. It is an excellent tool for determining the stress response and attitudes of the examined person. It allows to look at the team as one organism, diagnosing the organization's bottlenecks. Recent versions of the software are "intelligent in nature" and allow you to direct conclusions in the field of management (command) style on the basis of several trials at appropriate intervals relating to the trend.

During the research, a comprehensive program for assessing the natural potential and current capabilities of potential commanders or managers was used - IEMSS - (Integrated Enterprise Management Support System) based on the neuroleader concept. This system allows you to examine not only attitudes, but also the cause of stress or reduced work efficiency. Analysis of managerial attitudes with the use of the IEMSS system, which uses the instruments of thermoactive scanning and significantly supports personnel management, which translates into work results (efficiency) and increases the efficiency of the team.

Regulatory thermography according to the Heidelberg model has undergone many modifications, from its inception to today's scanning method. The history of TRD, as it was originally called (thermoregulation diagnostics), begins in the 1950s. Thanks to E. Schwam and Reehe, the first fundamental principles of thermoregulatory diagnostics were created at that time - subsequent changes in the temperature value in the infrared range are regulation, i.e. the reaction of a living organism to stimulation.

At Heidelberg University, a group of scientists around G. Heim and M. Blomhke developed scientific standards and procedures for measuring with a non-contact infrared sensor. However, this method has developed mainly as a contact method in many countries alongside the classically known medical thermography.

The Essence Of The Method Of Subcutaneous Micro-Radiation Scanning

The method consists in a non-contact measurement, with an infrared sensor, of the human body, which is subjected to a stress stimulus, which in this case is the cooling of the body, which is achieved by undressing the subject.

The method of examination can be compared to an ultrasound examination, where a probe, in this case an infrared analyzer, moves along the human body according to a specific procedure, collecting data, i.e. specific temperature values in the infrared range. In contrast to ultrasound, the probe does not come into contact with the body in this method. Three consecutive measurements are made in a fixed order and time. After the organism has reached a state of homeostatic equilibrium, according to W. Cannon's theory, the fourth measurement is carried out, which determines the biological "trend" of the organism, which is a fixed result vector of the basic group of

neurotransmitters. A series of values is then obtained, which are subjected to mathematical analysis in order to find a correlation between all the measurements (Fig. 2).

Fig. 2: A graphic image of the values resulting from the radiation, which were subjected to mathematical analysis to find a correlation between all measurements

Source: own study based on: K. Krupka (2018), Fundamentals of neuropsychosomatics, The basic set of information needed to work with the neuropsychosomatic process in the Leadership project, training materials (unpublished), Krakow

In the STRD study, not only the value of the infrared temperature itself is important, but also the trend and its fluctuations in a specific time unit. We call these changes the regulatory value or plasticity. Each measurement point on the subject's body has a specific value. As a result of stimuli (stressors - in this case, they are cooling the body down by undressing the patient and acting in contact with blood), a reaction takes place in the form of a change in the value of a given point.

Regulatory stiffness and limitations of tested plasticity

From the point of view of physics, each stimulus (stressor) causes an energetic reaction of the system, in this case the human body. Each point on the skin subjected to the stimulus can react in three ways. The value, that is, the temperature, may increase, which means that the point is warming up; the temperature may drop, i.e. the point cools down and the last possibility the temperature does not change. If all the tested points are sorted by value, from the lowest to the highest, and each of them is given a specific number, and then the observation is made as in time, i.e. during the next two measurements, they behave, then information will be obtained, which is called regulation. Regulation is the most important parameter of energy changes [4].

If the points with the highest values in subsequent measurements, i.e. the second and third, will have a lower value, we call it positive hyperegulation, if the same points heat up, we call it negative hyperegulation. This is due to the known fundamental laws of physics - no correct value can increase because such a situation becomes incorrect and suggests a pathology of a given function. Similarly, if the points with the lowest value in subsequent measurements, i.e. the second and third, will have a higher value, we will call it positive hyporegulation, and if the same points lower their value, we will call it negative hyporegulation. The same situation occurs in the case of hot spots, but it is a reverse reaction, i.e. a continuous drop in temperature is an incorrect reaction and also suggests a pathology of the function. There is still a third possibility, i.e. there is no change in the point temperature value as a result of the stimulus (stressor). Such a situation is called regulatory stiffness, the lack or a significant limitation of plasticity of the tested system [5].

Regulatory rigidity is the most disadvantageous regulatory situation. Failure to respond to the stimulus indicates information chaos. This state of affairs cannot last long. Therefore, there is always an attempt to explain this kind of reaction. It should be remembered that stiffness, in common understanding, is associated with something dead. In fact, it is so - because if the system does not respond to a stimulus, it is dead from the point of view of energy processes, i.e. it does not react with the environment [6].

The skin plays a decisive role in regulating body temperature. It consists of three layers: epidermis, corium and subkutis. Corium is the place in the skin responsible for creating and expelling skin heat.

Based on the segmental division of the body by the spinal nerve, the temperature and the skin's ability to react to stimuli become indicators of deeper localized disturbances in the functioning of the whole organism or its individual organs.

Human infrared radiation as an aspect of the surrounding thermal field is an excellent tool that is used to show the internal state of the human body. Changes in infrared radiation correspond to changes in microcirculation on the skin.

It has been proven that cutaneous microcirculation is a potential representative of the entire vascular bed and reflects its structural and functional mechanisms as well as general vascular disorders.

Elements of tactical medicine and motor activities of the examined

The battlefield is the stressful place. In addition to the primary tasks of each soldier in combat conditions, an important element is also tactical combat care for the wounded on the battlefield (Tactical Combat Casualty Care) [7]. According to TCCC guidelines, there are three main preventable causes of death of a soldier on the battlefield. The main ones are massive bleeding. The mere sight of blood causes shock and is a strong stressor. Therefore, for every soldier and battlefield rescuer, it is important to locate the hemorrhage correctly and stop it as quickly as possible [8]. As part of his activities, the battlefield rescuer has a number of activities to perform. Their order depends on both having knowledge and skills, the consent of the commander and making the right decisions [9]. The correct implementation of the algorithm is important for the effectiveness of actions. It is he who allows you to systematize activities and not make a mistake.

Methodology and stages of research

The activity profile of the laboratories at the Military University of Land Forces is focused on studying and monitoring stress among students. COVID-19-induced change and limitations in the research environment resulted in limitations in the study population. The aim of the study was to assess the reaction of a military academy candidate operating under the influence of stressors and their relationship with the radiation emission of selected neurotransmitters. The research methodology takes into account operation in conditions similar to natural (battlefield).

The aim of the study was to assess the correctness of the task performance according to a given algorithm (providing help on the battlefield) under conditions of strong stress and monitoring the concentration of selected neurotransmitters under stress and after reaching homeostasis. The study was divided into several stages.

In the first stage, training was conducted for the entire pilot group, in which each of the respondents carried out manual activities related to giving the first one on the battlefield under the supervision of an instructor. The first part was completed by checking the correctness of the exercise.

In the second stage, each participant covered a distance of 0.5 km with a weapon and ran into the room where the phantom was located, and followed the exercise algorithm. The temperature in the room (unknown before) was low (outside 32ºC, inside 9ºC), the sounds of the battlefield and the screams of the wounded were simulated. **At this stage**, the correctness of the activities leading to the placement of a tactical tourniquet on the bleeding limb (phantom) by the subject was assessed according to the algorithm assumed in the Tactical Fire Care phase, and the effectiveness and accuracy of the exercise in conditions similar to real ones was assessed.

In the next stage, the subject was tested using thermoactive scanning - STRD and the level of 4 essential neurotransmitters having a direct impact on personality was assessed. In the next stage (240 sec. pause), the subject completed a test assessing the type of stress to which he or she was subject (stimulating or instrumental). Figure 3 shows propensity to take a risk in the studied pilot group.

Fig. 3: Propensity to take a risk in the studied pilot group

Source: personal study

The research shows that half of the surveyed population shows a tendency to take risks, known as stimulation risk. It is seen as a way to provide yourself with stimulation by increasing physiological arousal. Profit, „win or loss" is not important here, because activity is supposed to cause a pleasant state of excitement, which is an end in itself.

The other half of the respondents showed a tendency to take instrumental risk, which is perceived as an opportunity to achieve a positive result. It is the future win that makes people look for such instruments to increase the probability of success.

Group selection, purpose and course of the study

The study involved 12 cadets, the first year of five-year military studies at the Military Academy of Land Forces. The respondents were subjected to training in the field of CLS (Combat Live Support), which included familiarizing them with the main assumptions of the TC3 committee and the algorithm of actions in the Care Under Fire phase.

The criterion for including students in the research was to complete a shortened training course in the field of CLS, including the assumptions of the TCCC Committee, activities in the Tactical Under Fire phase, where the main assumption is to find massive bleeding, put on a tactical tourniquet, and evacuate to the Tactical Fire Care Phase. The research tool to assess the quality of the algorithm's execution was the previously prepared evaluation sheet, containing all the elements of the algorithm included in the activities of the combat field rescuer in the Care Under Fire phase. The effectiveness of the stasis placement was assessed by the examiner by the lack of a pulse on the artery of that limb on which he had placed the tactical tourniquet (after locating the hemorrhage). Resting heart rate and heart rate after exercise were examined. The heart rate of each participant was measured using a Sanitas brand heart rate monitor. The first part of the research was carried out in a room where training in manual activities was previously held. The participants of the study were to perform activities according to the algorithm in accordance with the scope of activities in the Care Under Fire phase (without the introduced stress element).

After the training, analogous measurements were carried out on the same group of students. They were performed in a room equipped with devices simulating the battlefield. Each subject, wearing a backpack, a helmet and a tactical vest with a rubber weapon, was to perform a quick run around the building (500 m distance) before entering the room, after which, before entering the room, he was introduced into a tactical situation. In the room there was a helper, an injured-unconscious man, who had bleeding marked with artificial blood on his uniform on one of his limbs. As part of the cadet tasks, as in the preliminary study, he was to perform activities involving the Care Under Fire phase.

After the patient's hemorrhage on the limb was properly secured, using the CAT tactical tourniquet, checked in the meantime by the evaluating examiner, the cadet proceeded to the next element of the algorithm. The study ended with a command from the examiner. It was issued when the cadet decided to evacuate the casualty to the Tactical Fire Care phase. During the execution of the algorithm, the examiner entered individual elements made or not on the evaluation card, marking performed or not made.

Fig. 4 : The question was: Is there a relationship between the intensity of certain neurotransmitters and the style of command?
Source: personal study

The last element of the study was the measurement of neurotransmitter emissions using a non-invasive thermoactive scanning method - STRD. Each cadet was tested three times with 10-second intervals, which is in line with the methodology of such a study. Then, after 240 seconds, another (fourth measurement) was made to determine the trend in the style of command. The question was: Is there a relationship between the intensity of certain neurotransmitters and the style of command? - did not give clear answers. It therefore remains the subject of separate studies of command styles. Fig. 4 shows the above thesis and the intention to verify it in further research.

Summary

The pilot studies indicated that in the study population, four subjects did not make any errors in the algorithm. Five out of twelve respondents (i.e. 41.6%) did not correctly complete the task according to the assigned algorithm after putting on the tactical tourniquet (they did not check the rest of the limbs for massive hemorrhages). Three subjects made mistakes under the influence of a stress factor (they used their tourniquet, not the injured person, to stop the bleeding from the limbs).

Research has confirmed the thesis that distress is the body's response to a threat and it does occur when the stimulus, i.e. the stressor, is triggered. Moreover, the research showed the influence of eustress on the respondents as positive and mobilizing to action, and the influence of neustress as a stimulus for a given person who was neutral in action, which for others was an eustress or distress stimulus. Managing stress as cognitive and behavioral efforts to manage, reduce, or tolerate external or internal demands has taken a stimulating or instrumental form. In the risk trend study, the population distribution was 50/50. Elevated dopamine levels were observed among four students, and acetylcholine among two. This can prove a lack of concentration and an escape from making decisions under conditions of high stress. In one of the subjects, the concentration of gamma-butyric acid (GABA) was above the mean for the studied population.

To sum up, many years of research on stress confirm its variable role depending on the intensity, number and type of stressors. This is consistent with the research carried out on the student population of the Military University of Land Forces. Operation in conditions similar to natural (battlefield) supported by IT devices for stress assessment correlated with the radiation of neurotransmitters (dopamine, acetylcholine, GABA and serotonin) indicates the need for further studies on a larger population to assess and reduce stress in students through regular scanning using devices STRD.

Abstract

Integrated Management Systems (IMS) facilitate the achievement of objectives by organizations. However, their effectiveness depends on many variables: their degree of use, type of activity, expertise of employees, etc. They can become a basis for innovation, reducing costs, increasing production, improving quality and relations with stakeholders. On the other hand, errors at the stage of selecting a specific solution and its implementation may make them look like unjustified expenditure. The aim of this work is to present the process of selection and implementation of an IMS on the example of a manufacturing company. The authors used case study method. The article presents a pre-implementation analysis, the process of selection and implementation of an IMS.

Keywords: Integrated Management Systems, Implementation.

Introduction

The processes of acquiring, collecting, processing and using information can determine not only the growth but also the survival of a modern organization. It is essential to have a resource of information about the developments on the market, possible partners, the ways in which competitive companies operate, customer needs, suppliers, demand for a particular commodity, etc. This data is obtained from various sources, but in order for it to be valuable, it must be appropriately processed. This is supported by a computer, which is widely used today, from simple office work to production support and management of the entire company (Amrani et al, 2020; Lopez et al, 2020).

For this most important (from a strategic point of view) task, computer-integrated management systems (IMS) are being developed. Such a step will help, among other things, to improve the process of information flow and, consequently, to carry out tasks more effectively. It is a big step forward because companies suffer significant losses due to repetition of the same activities, which results in poor performance, uninformed employees, managers and customers (Tsesmelis et al, 2020; Zaloga et al, 2020). The key to success is the selection and then implementation of an IMS.

Matching the right IMS to the company's needs is a complex process. The right choice will result in improved management, simplified business process flow and increased revenue. However, in case of a mistake, the company will be exposed to errors in the processes being improved and deterioration of relations with stakeholders (including customers), which will result in financial losses (Amrani et al, 2020; Dellagi et al, 2020).

The first thing to do is to become familiar with the nature, objectives and functioning of the company. The pre-implementation analysis, or more precisely its result will lead to the preparation of the project of implementation of the IMS in the company. The analysis will provide an opportunity to take a closer look at business processes and, if necessary, improve their functionality by means of re-engineering. In addition, it is possible to gain knowledge about the expectations of the new system, goals, scope and critical points of its implementation. Collecting the aforementioned information will allow to define the criteria and proceed to the selection of the system for the analysed company.

The aim of this work is to present the process of selection and implementation of an integrated management system on the example of a manufacturing company. The authors used case study method.

Company Analysis

The analysed company is a manufacturer of special machine tools for the railway industry and belongs to global companies in this sector. It also produces specialist equipment for customers in the steel, paper and energy industries, using an extensive network of dealers around the world. The company works on modernizing and expanding its assortment by means of its own designing capabilities, as well as with the participation of foreign investors, who become its partners by introducing their own designs of machine tools that were not manufactured by the company before. This particularly applies to American and French companies, which provided the organization with access to the market of gantry milling machines, lathes, drilling and milling machines, modular machining centers for the automotive industry, etc.

The selection and implementation of an appropriate IT system for the company in question is a strategic decision which has a significant impact on the way the company operates and its development opportunities.

Pre-Implementation Analysis

The pre-implementation analysis is a series of activities leading to the preparation of the IMS implementation project in a company. It aims at determining the functional and technological guidelines which are the basis for selecting the system, taking into account the functional scope, development possibilities and price. Thanks to it, the objectives of the implementation project, implementation strategies, its process and organizational scope, as well as technical factors necessary for the project implementation are developed (Moś, 2012; Wieczorkowski, 2016).

Benefits of a pre-implementation analysis (Korzyści płynące …):

- defining implementation objectives,
- defining the scope of implementation (departments, persons, business processes and decision-making schemes),
- adapting the implementation strategy to the requirements of the company,
- defining the data to be exported or imported into the IT systems in place,
- highlighting critical areas of the implementation,
- calculation of implementation costs.

The scope of the pre-implementation analysis (Flasiński, 2006) may vary depending on the methodology adopted, but regardless of the choice, it involves the following steps (fig.1):

1. Description of business processes.
2. User requirements analysis.
3. Analysis of the organization's IT infrastructure.
4. Scheme of project definition.

Fig.1. Stages of the pre-implementation analysis

Description of Business Processes

Business process modelling is designed to provide answers to the following questions: How does the organization work? What processes are implemented by the company? Are the implemented processes effective and efficient enough? Is it possible to improve the processes being implemented? Are the processes implemented by the company compliant with strategic objectives? (Flasiński, 2006).

The main purpose of modelling is to understand how a company operates, to analyses its operations and to suggest possible improvements. Process modelling allows us to move away from "manual" management of the company, which is undoubtedly not conducive to the company's growth, creative environment and commitment of employees. The transition to process management allows companies to gradually activate their employees (by assigning them the roles of process owners) and to use their potential to the maximum.

The main benefits of process modelling for organization include for example (Korzyści płynące…):

- a uniform description of the company's operations,
- strong focus of the whole company on achieving customer satisfaction,
- identification of the best (in terms of time, resources and costs) way of operating a company,
- improved communication and cooperation within the company as well as the organizational culture and working atmosphere,
- preparation for the development and easier implementation of the Quality Management System,
- preparation for the implementation of a workflow-type system and management of electronic company resources (including documents),
- identification and classification of areas for improvement, allowing for continuous development of company's operations,
- arrangement of the processes implemented by the organization, improvement of the processes implemented in terms of time and money.

An example of modeling the process of selling goods and suggested process improvements are presented in Figures 2 and 3.

For the purpose of the pre-implementation analysis, all main and auxiliary processes taking place in the company are presented in a graphic form.

The suggestion is to create an additional customer database in which, in addition to basic personal data, information on concluded transactions will be recorded. On the basis of the data, it will be possible to determine whether a given customer is a debtor to the company (if they have not settled all payments to the company). Thanks to this, it will be clear whether to cooperate with a given customer or refuse to carry out an order until they have settled all payments. In the case of a customer not included in the database (new customer), the solvency will be checked using the available methods.

Fig. 2: The process of selling goods

Fig. 3: Suggested changes in the process of selling goods

Analysis of the organization's IT infrastructure

The next step is to review the organization's IT base. Knowing its current status will be essential for the selection and implementation of the new system.

- Servers - a database server, a server with IMS and network division, and a server with a backup copy of the system and database.
- Workstations - there are about 150 PCs in stock, including laptops.
- Intranet service - the company has its own Intranet network. All employees of the company have access to this network. They can use websites, electronic mail, as well as two extensive areas: Quality Management System ISO 9001:2000 (quality manual, quality manual - archive, organization chart, list of procedures and instructions, list of procedures and instructions - archive, process flow diagram, quality policy and current affairs: (news, company website, employee periodic evaluation system, SIMPLE, company phonebook).

Software supporting designing:

- EdgeCAM - a tool for programming the CNAC machine tools (EdgeCAM),
- SolidEdge - Solid Edge is one of the leading systems for 3D computer-aided design. The application enables to create three-dimensional models of whole elements and individual components (Kisielnicki, 2008; Solid Edge).

Office software:

Microsoft Office software package. Basic and additional programmes**:**

- Excel,
- PowerPoint,
- OneNote,
- Access,
- Outlook,
- Project (managing the project schedule),
- Project Server (project management at the organization level).

Selection of the IMS

Choosing the right IMS will result in improved management, simplified business process flow and increased revenue. However, in case of a mistake, the company will be exposed to confusion in accounting, worsening of relations with customers, which will result in financial losses. Knowing the great benefits as well as the serious consequences, it is worthwhile to approach the considerations on this subject professionally and allocate the appropriate amount of time and resources to them.

System Selection Procedure

Depending on the type of enterprise, situational factors are considered (including development plans and initial preparation of the organization for change) and the plan and scope of activities is adapted to needs (Adamczewski, 1998; Adamczewski, 2003; Grudzewski and Hejduk, 2004).

Basically, the entire selection process involves the following activities: feasibility study of the project, development of requirements for the IT system, bidder selection, contract negotiations and implementation (Fig. 4).

Fig. 4: System selection procedure

Feasibility Study

A feasibility study is an analysis of the possibilities of investment activities by assessing and identifying possible limitations. It comprises two main elements (Olszak and Sroka, 2001):

- strategic analysis - an analysis of the strategic business objectives and the resulting goals set before the implementation,
- the assumptions and definition of the constraints in terms of technical, financial, organisational, time constraints of all parties involved, the knowledge, skills and attitudes of the management and employees, the possibilities of using external funding.

The selected system will be implemented for several (up to a dozen or so) months, and only after that time its operation will begin. Sometimes it happens that various restrictions may lengthen this process even to 2 - 3 years. The company's activities during this period will be continued and the planned organizational changes will be implemented earlier. These changes should be taken into account during the selection process in order to be guided not only by the current needs of supporting the organization but also by future needs.

At the end of this stage, the summary report should provide the company's management with the information concerning: objectives, assumptions, constraints, initial schedule and framework budget of the project. This result presents the internal and external conditions of the organization and possible scenarios for action. On its basis, decisions can be taken to start preparatory work for the investment.

The start of the project and introduction of new tasks requires the company's management to appoint the sponsor and manager of the project. Their task will be to make decisions preparing for the implementation, so they will become part of the team responsible for implementation. One person should not perform both functions, as these tasks will be significantly different and, at the same time, valid for the entire duration of the project.

IT system requirements and system selection based on the requirements

Preparation for the evaluation of numerous offers requires commencing works, the result of which will be an appropriate definition of the selection context.

Defining the requirements for the new system and the selection process are carried out according to the following steps:

1. Analyzing the current and defining the target support needs - implemented as a functional or process analysis - it should cover the company's activities as a whole, regardless of the planned scope of support for the new system. It should show the current condition of the company, then take into account future needs and in this form be the basis for the evaluation of the suggested solutions.
2. Appointing and substantive preparation of an internal team – this team together with the project manager will make a detailed evaluation of the received offers in terms of their substantive compliance. It is usually recommended that the team is composed of representatives of the functional areas covered by the system, who have an important role to play in these areas, provided that they are not the persons leading these teams. The main task of the group is to work out, on behalf of future users, which of the considered applications could best support operational activities. It is advisable to prepare the team for further work through training that covers such issues as (Knosala, 2007):

- project and project management vs. current company objectives,
- integrated IT systems,
- evaluation of IT solutions and the process of solution selection within the company,
- multi-factorial evaluation of offers - methodology of the procedure.

The internal team develops and comes up with a proposal for approval: criteria for evaluation of offers, requirements for presentation of applications, a detailed analysis of the possibilities of individual applications and conclusions from completed stages. Next the team, through its manager, decides on the most advantageous offer. After the selection and start of the implementation, the group usually transforms into an implementation team of the investor cooperating with the consultants of the implementing company.

System Selection Criteria

Currently, there are plenty of ready-made solutions for IMS on the market, which gives a good choice but also increases the probability of making a mistake. The most popular solutions on the Polish market have been considered. The information collected on the group of applications under consideration should provide answers to the following questions (Adamczewski, 2003; Bojarski, 2003):

- industry - the basic aspect determining the selection of a system is its substantive compliance with the nature, mission and needs of the company. In addition, in the case of a production company (this is what we are considering), it will be important to analyses the types of production systems taken into account by the integrated system's production organization and control module. A system that is only adapted to discreet manufacturing should not be implemented in a company with continuous production and vice versa,
- system advancement - this is particularly important when selecting the systems to be considered as well as in subsequent consideration which one to choose,
- hardware and software requirements - check and collect information about currently used software and hardware,
- scope of the system (supported business processes) – when considering the choice, one should take into account whether the implementation of the entire system or only the most needed modules is considered. In order to establish this, the areas indicated as optional as well as necessary to be served should be selected. The result of the pre-implementation analysis, showing the specificity of the activity of the company in question and the main process flow, will prove helpful,
- flexibility, communication - is an important issue and should allow for its expansion in case of increasing the amount of data and adding a new module (compatible with the rest of the modules),

- functionality - it should be closely examined because without it, it is impossible to save the working time of personnel, which is one of the reasons for acquiring this system. It follows that the fundamental, and even the most important, criterion should be the relation between the effective functionality of the solution and its price,
- access to updates - access to upgrades and new versions,
- implementation history - attention should be paid to the number of successful implementations of a given system in previous system users,
- price - plays a significant role during the selection,
- terms and conditions of the contract - the terms and conditions of the licence agreement and those concerning the course of implementation and warranty and post-warranty service should be taken into account. Another important issue is the possibility of contacting the service, as rapid intervention is necessary in the event of problems with the system.

Review of the considered IMS

So far, the procedure has been presented and the criteria have been established, so we can move on to the right part - choosing an IMS. Before starting to consider, a list of companies proposing their solutions should be created. If all the companies currently available on the market were taken into account, it would be impossible to take a closer look at them. This would result in an unreliable selection of applications. Five, which according to the rankings are the best and most popular, have been taken into account. In each item, categories have been created according to which we will evaluate the compared applications:

- IFS Polska,
- REKORD,
- SAP Polska,
- SYMFONIA,
- TETA.

Comparison of the systems

The list of properties of the solutions under consideration provides answers to certain questions and may even indicate a leader, but it is not the only or the most important indicator of choice. We select the application for a particular company, which invests huge amounts of money, devotes the time of many employees and even risks its market standing. It does not care about being able to boast about having the best system, but about the profits it is supposed to make in the near and distant future. To succeed in this, the characteristics of the organisation, its objectives and needs must be taken into account when considering a choice:

1.It is a medium-sized manufacturing company, a global manufacturer of machine tools, lathes and milling machines.
2.The aim of the organisation is:

- to expand its activities mainly to Western European countries and to sell products and services of a quality that meets the expectations of customers; the company intends to gain new partners who would support it in activities involving the improvement of technology and research projects,
- to change the production process, work organisation and human resources management,
- to develop new technologies,
- to attract investors and apply for funding.

The chosen philosophy of selection presented by the relevant criteria is shown in a table. Such visualisation will be appropriate for the sake of transparency and ease of implementation of possible changes.

The content of the table is made up of individual applications and subsequent selection indicators. They have been prioritised and weighted in order to further distinguish their value. The scale of the weight as well as the scoring of each item is from 1 to 5. This solution allows for the use of values from the whole range of the scale, and does not exclude the candidate in case of obtaining even a very low score from one criterion.

The final score is calculated as follows:

(SCORE_1 * WEIGHT_CRITERION_1) + SCORE_1 * WEIGHT_CRITERION_2) + (SCORE_3 * WEIGHT_CRITERION_3) + … + SCORE_n * WEIGHT_CRITERION_n)

The system with the highest number of points will be highlighted and taken into account for further consideration (tab. 1).

Table 1: Comparison and evaluation of systems

Evaluation criterion	Weight	Ifs Polska	Rekord	Sap Polska	Symfonia	Teta
Industry and company size	5	4	5	4	3	4
System scope	4	4	4	5	4	4
Functionality	4	4	5	4	3	4
Equipment and system requirements	3	0	2	5	4	4
Access to updates	3	2	2	3	3	0
Implementation history	2	5	4	5	4	5
Total points	-	69	81	91	72	74

Implementation Strategies

An IMS, although it is very expensive, in many cases brings great benefits to the company deciding on it. A prerequisite for the success of the process of improving management in a company is good planning - from the idea for the system to the last day of its implementation. One of its most important points, and even a milestone, is the selection of the implementation strategy. We can choose between the following:

- a radical implementation - a complete and simultaneous replacement of the existing system. It is characterised by the shortest implementation time and the lowest costs, but high risk. If it fails, it will cause very large losses,
- gradual and complete implementation - a complete introduction of a new system, in parallel, for a specified period of time, to using the existing system. Compared to the previous strategy, the time is longer, the costs are higher, but the negative effects of failure are reduced,
- gradual and modular implementation - introduction of a new system, one module at a time, with the new module replacing the analogous module of the previous system. The time is longer and the costs associated with the implementation are greater than in the other two strategies, but the possibility of failure of the project decreases.

An analysis of previous operations and knowledge of the current IT situation, which is its consequence, will make it possible to detect errors and avoid them in the future. The rapid transfer of existing tasks to a new application has resulted in: a change in the existing order, innovative problem solving, confusion among the employees, taking many man-hours to master the "smart" software. When implementing the system, the company's and employees' nature should be taken into account. It is a state-owned company (over 50% of shares) with "aged" staff. This means that the majority of employees have not previously had to deal with computerisation, and thus information technology. Only a long-term further education could bring the acquaintance and familiarity with the new solution, which is IMS.

A "gradual and modular" implementation was chosen as the most appropriate strategy for the selected company. The advantages of this solution:

- bad company experience with the competing options,
- employees requiring training,
- low risk of failure

The downsides are:

- long implementation time,
- higher costs than in the case of the other options.

The next stage is to establish the order in which the modules will be implemented and to estimate the dates of subsequent stages and the entire implementation process. There are six modules to be implemented (fig. 5): finances and accountancy, fixed assets, production process, turnover of goods, HR, customer service (this is about functionality, in a specific solution the above names may have equivalents). It is suggested to begin with the worst performing area in the company - turnover of goods, then the production process and the next would be customer service.

Fig. 5: Order of implementation of the modules

After proper implementation and training of staff, the costs are paid back and, over time, profits are made. However, this is not certain, and that is why the important and necessary issue that the management of a company has to do is to ask the question: is it worth carrying out such a serious investment process, or is it better to give up the idea of carrying it out? (Werner, 2004).

The foundation of any investment activity is considered to be the acquisition of specific profits, which are documented by economic accounting and correspond to the target set by the company at the beginning of the project.

SAP All – In – One – implementation

A decision has been made to implement the SAP All - In - One solution. The SAP solution for the electrical machinery industry contributes to the optimisation of key processes within the company, ensuring the quality of the design, production and assembly processes, timely delivery of products configured in accordance with customer requirements and improving the quality of maintenance services. It enables a high level of customer and maintenance services (SAP…).

Business benefits for the managing director:

- support in the customer service and sales process,
- improvement of business processes,
- information on current financial status and budget control,
- control over the company's development strategy.

Benefits for the financial director:

- fast preparation of necessary reports (possibility to export them to MS Word and MS Excel),
- monitoring of the company's financial situation,
- control of the budget.

Benefits for the chief accountant:

- possibility to book documents according to European standards,
- saving up to 80% of time (most functions are performed automatically by the application), less risk of error,
- easier reporting.

The key arguments in favour of implementing the system in the company:

- employees will be able to make more accurate and quicker decisions,
- the efficiency of work will be increased, which will translate into greater profits for the company,
- the company will become more "competitive in the European market" - the system works according to European standards, business transactions can be concluded and reported in multiple currencies,
- reduction of production costs, reduction of stocks,
- improving the efficiency of the logical system,
- a clear division of tasks,
- improving the quality management system.

Summary

The development of technology in the second half of the 20th century, which initiated the era of computerisation, has radically changed the way businesses operate. It brought many innovative solutions that improve the efficiency, profitability and relieve the burden on employees (Kosiński, 2001). It resulted in many benefits and created new standards. Companies that want to dominate the market, or at least survive, cannot be indifferent and must keep up with new solutions and technologies. This is not easy, because technology is moving forward at a frantic pace. What is good today may turn out to be useless tomorrow. Keeping up requires more and more human and financial resources, and sometimes this is not enough.

A perfect example is the change in the way a company is managed. This area is the "brain" and "senses" of the company, which makes it crucial. It all relied on observation, analysis and transmission of information by one or several people. This function was taken over by computers with different types of software, depending on the department. Currently all tasks are performed by one comprehensive application called an IMS (Carvalho et al, 2020; Zaloga et al, 2019).

The systems in question are a tool facilitating and accelerating work. But their effectiveness depends on the degree of their use, type of activity and employees' knowledge (Skuza and Prusak, 2018). They can become a basis for innovation, reduction of costs, increase of production as well as improvement of quality and relations with customers (Cieśla and Gunia, 2019; Marta and Rastislav, 2018). However, when they are not used in the company, they are become unjustified expenses.

Abstract

The crisis caused by Covid in 2020 has shown how suddenly the market situation and society can change. Many managers did not expect such a sharp and rapid crisis after a decade of economic growth. Some businesses crisis has caught unprepared. The sharp decline in turnover due to government restrictive measures has caused an acute shortage of liquid assets in most companies. The company can go through a similar crisis by creating an anti-crisis plan, which describes the reactions to individual adverse market situations that may occur. This gives managers the advantage of pre-built sets of measures that they can apply immediately, making their responses more flexible. The most important and most used tool is cost reduction. When identifying possible savings, cost controlling is important, which gives us important information about the cost structure in the company. Modern cost management methods such as ABC identify activities in the company that can be limited or eliminated altogether.

Keywords: Cost Controlling, Anti-Crisis Plan, Cost Management.

Introduction

At a time when the whole world is struggling in an economic crisis and competition is stronger than ever before, proper and effective cost management is essential, even in the smallest business. The period of crisis is a huge test of the stability of all businesses across the economy. It is during this period that it is necessary to adapt to the current situation from day to day, from hour to hour. The crisis in 2020 caused by the spread of the virus from China to the whole world came very suddenly and unexpectedly. While ordinary economic crises can be predicted as various macroeconomic indicators often indicate an overheating of the economy, a crisis caused by a virus is almost impossible to predict as it spreads very rapidly across continents. During such period it is essential for every company to have emergency plans and strategies in place, which will help the management to make decisions in a certain line and not succumb to panic. As the health crisis is characterized by strict government intervention in the functioning of the economy, it is necessary to adapt flexibly with the greatest possible effort to reduce unnecessary costs. Competition forces entrepreneurs to constantly look for new ways to make a profit, but in the event of a crisis, reducing losses can quickly become the main motivation for entrepreneurs, especially if the state has ordered them to close down or restrict operations.

Objective

The objective of this article is to determine the role of controlling costs in the implementation of anti-crisis strategy for enterprises, identify sectors of enterprises most affected by a sudden crisis, identify opportunities to mobilize cost reduction reserves through newer cost control methods, including process-based planning and cost control methods.

Methodology

Several scientific methods were used to achieve the objectives of the work. Based on a literature review, suitable domestic and foreign publications were used. Data, used in the processing of this article, were obtained from relevant official sources. These data were processed using several scientific methods, first analysis was performed, then cross-sectoral comparison and time comparison were used. Based on the resulting data, synthesis and deduction were used.

Government Restrictive Measures

In addition to the restriction of forced closures of the most common types of business, most often service companies and the retail sector, where the largest number of people met, the state imposed new obligations on companies not affected by the restraint measures. For example, in the Slovak Republic, the state, through the Public Health Authority of the Slovak Republic, ordered establishments that did not have to interrupt their activities, providing, for example, disinfection or gloves on entry, limiting the number of customers per square meter of operation, ensuring regular disinfection of facilities, wet floor cleaning every day, etc. These measures, especially at the beginning of the crisis, caused an enormous demand for disinfectants, gloves and other protective equipment. The market response to this change in demand was a dramatic increase in the price of these products. Thus, there was an unpredictable situation where state intervention forced companies to increase their hygiene costs, which the cost strategies of the companies did not envisage. In the European environment, companies have not yet encountered this form of crisis. The last time they were severely tested by the economic crisis in 2008, when they were not forced to limit their operation from day to day, or to limit the capacity of customers etc.

During the strictest measures during April were forced to close for example, restaurants, accommodation services, small shops, services such as fitness centres, wellness and spa, ... due to restrictions issued by the Public Health Authority of the Slovak Republic (hereinafter referred to as the ÚVZSR). (Úrad verejného zdravotníctva SR, 2020) The effect of this measure was almost liquidating for many companies, as their sales immediately fell to zero, and only a few of these companies were prepared for such a situation. In times of a positive economic situation on the world market, many companies have invested their free funds in new areas, projects, development, etc. and did not hold sufficient liquid financial assets. The sectors most affected were mainly small and medium-sized enterprises, which had great problems obtaining funds to cover costs such as rent, energy, wages, etc.

Analysis of the impacts of the Covid crisis on the affected sectors in the Slovak Republic

According to government regulations, the most affected companies were service companies, namely accommodation, restaurants, bars, and companies providing sports activities. These companies were completely banned from any activity. These restrictions were reflected in a great loss of turnover in these sectors.

Fig. 1: Turnover of selected sectors in 2020

In the accommodation sector, turnover decreased by a staggering 84.7% compared to the same period of the previous year. In the food and beverages sector, turnover also fell very significantly by 42.1%. According to the data of the Statistical Office of the Slovak Republic, a total of 98.3 thousand people were employed in these sectors of the economy before the crisis. The decline in turnover also affected the labour market and employment in the individual sectors affected fell. The drop in accommodation is more significant compared to restaurant services, as government allowed the operation of restaurant services to be at least partially resumed after a few weeks of lockdown.

Fig. 2: Employment indices in selected industries by months

As we can see in the graph, the largest drop in employment was recorded in the accommodation services sector, where employment fell by 18.9% year on year. The restaurant services sector also recorded a decrease of 13.4%. This decline would probably be greater, but during April, restaurants were allowed to at least dispense food through the counter and offer food delivery. Other sectors of the economy recorded only a slight decline of about 5 percentage points. However, the crisis has also brought opportunities in the postal and courier services sector and in the information and communication sector, as the government's measures were aimed at restricting the movement of the population as much as possible, a so-called lockdown occurred. Thus, consumers had to meet their demand through online stores, which experienced a huge increase in orders during the lockdown. For this reason, companies involved in the online sales chain had to increase their human resources capacity as well.

However, global unemployment has risen as companies prepare for declining demand in uncertain times and one of the first measures is to limit the recruitment of new employees or re-evaluate already concluded contracts.

Fig. 3: Unemployment, % of active population

The data show that the increase in e-commerce activity in the sector could not cover the decrease in services and other sectors concerned. Before the start of the Covid crisis, the Slovak Republic reached the historically lowest unemployment rate. As we can see from the graph, the rise in unemployment is still just as sharp, so for now we can only predict where it will stop.

Due to the extent of the pandemic, which broke out worldwide, in addition to domestic demand decrease caused by regulations of the Slovak government, foreign demand also decreased, which is very unfavourable for the Slovak economy due to the fact that it is based mainly on exports.

Fig. 4: Total export, mil Eur

According to the data of the National Bank of Slovakia, in April, when government measures were the strictest, exports fell by 45.9% compared to the period before the measures were introduced. We can see from the graph that this decline was caused mainly by artificial factors (restrictions) and not by natural economic phenomena, as immediately after the release, export restored almost to it's original values.

The biggest problem: lack of liquidity

Businesses need to have financial reserves in case of adverse circumstances, but many entrepreneurs underestimate these reserves, especially in times of economic growth, they do not anticipate such a massive crisis that would come so quickly. (Briciu and Sas, 2009) During an economically favourable period, many companies invested in business expansion or new technologies, often financed by loans, which were extremely cheap due to the ECB's strategy to maintain economic growth in euro area countries with an inflation target of 2%. (Rostagno *et al.*, 2019) Shortly after the start of the Covid crisis, caused by the introduction of restrictive measures by the state, many companies struggled with negative cash flow. While sales were significantly reduced, often to zero, costs such as rents, wages, energy, etc. had to be paid in the usual amount. Due to these circumstances, many companies that underestimated the creation of reserves soon ran out of liquid assets.

Fig. 5: Number of requests for deferral of corporate loan repayments (number)

(Národná banka Slovenska, 2020)

The end of April brought a more significant increase in the number of requests for deferral of payments. By mid-May, almost a fifth of the applications had been approved. Applications began at a slow pace in the second half of March. The end of April and the beginning of May have already brought a significant increase in the number of

applications submitted, the total number of which reached almost 7.5 thousand in mid-May. So far, almost 14% of companies financed by the domestic banking sector are interested in deferring payments. In the second half of April, the banks began approving these applications, and by mid-May, half of them had been approved.

However, the situation may be even worse, as it takes time to reflect negative results in companies' financial reports. According to Saxunová and Chorvatovičová (2016), timing and management of expense recognition might influence company's profit and hide possible warning signals in the company financial statements. Financial markets would then negatively react towards these warning signs like decreasing trend in profitability. However, according to Papík and Papíková (2020), such management interventions must not lead to the use of incorrect accounting procedures, which could lead to a financial restatement due to accounting errors. In addition to the costs of removing these errors, adjustments to the financial statements also have an impact on the company's reputation and, in the case of publicly-listed companies, on their market value.

If an enterprise has accumulated short-term financial resources, whether in the form of cash, bank accounts, or other short-term assets, those resources may be used to cover operating costs. However, if it does not have short-term financial assets, it becomes insolvent. According to available data, before the outbreak of the pandemic, there were approximately 7% of companies in Slovakia that had a negative operating margin and at the same time were not able to cover their fixed costs with short-term financial resources.

Fig. 6: Enterprises with revenues not covering costs (% of the total number of enterprises, year 2018) (Štefan Buchta, Lalinský and Radoslav, 2020)

From the above data, we can conclude that the fastest liquidity problems will affect small businesses that do not have sufficient current assets to cover the no-revenue period. These data suggest that these companies will also have major difficulties in obtaining potential loans from banks to bridge the crisis.

Anti-Crisis Management

In good times, every company should also remember the risk of a crisis coming, which could negatively affect its economic results. Crises can have different causes and different effects with different strengths. The economy is a functioning cycle, where times of recession regularly appear, for which companies must prepare. An important part is to identify crisis plans and strategies so that management can respond flexibly to a rapidly changing situation. The speed of response can be a decisive factor that significantly affects the course and effects of the crisis on a company. As the crisis is due to external factors beyond the company's control, it is not possible to prevent a crisis, but it is necessary to apply appropriate measures to minimize its negative effects. Anti-crisis management is a process that focuses on applying measures before, during and after a crisis in order to minimize the impact on society.

It consists of 4 consecutive phases:

1. Crisis prevention - the company seeks to prevent crises, at least to the extent that it is able to influence ongoing market fluctuations. In the case of large multinational companies, they can to some extent affect the situation if the crisis is only within the industry.

2. Crisis preparation - at this stage, the company is preparing anti-crisis plans, strategies and measures to reduce the negative impacts.

3. Implementation of anti-crisis actions - the company applies and implements the plans it prepared in the previous step. It is important to implement the measures in a coordinated and gradual manner at the most appropriate time.

4. Evaluation - in the final phase, the company evaluates and verifies the implemented measures and their effectiveness and gathers new acquired knowledge and experience for future use.(Starosta, 2014)

It is also important to correctly and timely recognize the coming crisis, as this can give the company important time to prepare and implement austerity measures, which can give it a competitive advantage over other companies. This phase of crisis management is often the most challenging: to realize that a crisis does exist. Executives who refuse to face reality can significantly exacerbate the effects of this crisis. Managers sometimes misjudge the nature of the problem and focus on the technical aspects ignoring the issue of perception. But often the reason for the beginning of the crisis is the public's perception of the situation. (Augustine, 1995)

Cost reduction as the most important tool of anti-crisis plans

Cost management is having priority importance for all business entities, as profits increase mainly by reducing costs. Based on a study by Anna Starosta from 2014, which researched anti-crisis measures and strategies of companies during the last major economic crisis in 2008, we can conclude that cost reduction was the most used tool for companies in combating the economic downturn. The study was conducted in the V4 region on 60 Polish companies with more than 249 employees. The study shows that financial management is generally the strongest tool for companies. It involves more precise management of costs and expenses, a change in their structure and a systematic reduction. There is also great potential for cost reduction in the area of human resources. Up to 28.3% of entities started to reduce wage expenditures, the further reduction of expenditures was caused by a change in the organizational structure, which led to the abolition of some less necessary job positions and the subsequent dismissal of employees. As many as 51.7% of companies have taken this radical step. Companies had to proceed with an in-depth analysis of the expense structure in order to gain effectivity and reduce it.

Fig. 6: Analysis of taken anti-crisis measures during 2008 economic crisis (Anna Starosta, 2014)

Most companies take advantage of cost reductions for simplicity and speed. Finding reserves in the cost structure is easier for companies and especially faster than other measures. While, for example, increasing revenue is a longer-term process and, moreover, is not fully in the hands of the company, cost reduction is immediate and depends only on the decision of managers. To identify cost reduction reserves, as part of crisis management, the current accounting system must be reviewed. The anti-crisis strategy should implement cost control system. A scientific and practical problem is the need to set up the key components of these systems, which would take into account the specific features of activities in crisis situations. (Starosta, 2014)

Savings in wage costs must be made possible by an organizational structure that is sufficiently flexible. Flexible organizational structures are considered to be those that are less formal and flatter. Employees are a living part of society, flexibility lies in the fact that often employees find more efficient ways of doing work activities that go beyond formal regulations. (Natalya, 2014)

Modern Tools of Cost Management

To ensure the management of the rationalization of business costs, it is necessary to introduce cost control tools as part of crisis management. Cost management generally includes a set of targeted measures to influence the structure of costs, their dynamics and behaviour in order to reduce their level. Cost controlling is an important part of cost management. In order for costs to be used as a tool for business management, we must first know their nature, origin, dependence of costs on production, as well as their structure and composition. The occurrence of costs is monitored as the emergence of an economic category and the occurrence of costs of a particular product in the company.(Amir, Auzair and Amiruddin, 2016) The manager should know what costs were incurred, where they were incurred, what they were incurred for and who will pay them. Various cost control methods and tools provide answers to these questions. It is important to know the structure of costs, their division into individual internal business units, processes and outputs. A significant impact on the level of costs will usually be achieved after a certain period after the introduction of appropriate control tools. (Bogyová, 2011) Controlling is understood as a subsystem of the management system, which helps to achieve the goals, prevents possible dangers in time, requires effective management measures to be eliminated. We can characterize it as a specific form of working with information, where the task is not to manage real processes in the organization, but to manage the entire organization through information about real processes. Without controlling, constantly monitoring actual and planned costs and input and output costs, we cannot talk about effective financial management of the company. (Foltínová, 2007)

Preliminary calculations are the basic tool of cost management. There are many different types of calculations and cost calculation methods used in cost management. Cost management information systems can be divided into two categories:

a) functional based,

b) activity based.

Modern approaches to cost management and costing include Activity Based Costing (ABC), Life Cycle Costing, Target Costing and Just-in-Time.

Activity Based Costing (ABC) is a cost management method based on assigning costs to individual activities. It is one of the most accurate methods, but it is more resource intensive. It gives us the answer as to which activities consume the most resources. ABC system tends to be tracing-intensive.

Life-cycle costing focuses on monitoring costs during the various phases of the product life cycle. Costs are different at each stage of the life cycle. About 90% of the costs are incurred in the first phase - development.

Target costing focuses on determining the total life-cycle cost of a product, with the target cost being the difference between the selling price, which will ensure a sufficient market share, and the required profit. If the target cost is lower than the real achievable costs, the task of management is to find ways to reduce costs, while maintaining the same functionality for the customer, so that the current costs move closer to the target cost. (Cooper and Slagmulder, 1997)

According to accounting standards, the object of costs is a product, work, service or type activities of the enterprise that need to be determined costs associated with their production or performance. Cost accounting can also be done in the context places of their origin, centres of responsibility structural units. The problematic part is the correct transformation of costs according to the place of their occurrence to certain products. Various non-productive unit processes and operations are often carried out, which have an impact on ensuring the quality and competitiveness of the final product, which can entail significant indirect costs for non-production units that cause loss of profitability for certain types of products or the company as a whole. A necessary precondition for the correct distribution of costs for certain types of products is their accounting and grouping according to individual types and places of occurrence. Improper distribution of costs to individual entities leads to misallocation of resources, mispricing, reduction in the cost of producing cost-effective products, and vice versa. (Hansen, Mowen and Guan, 2007)

The ever-increasing competition in the market puts pressure on cost and cash flow management. This pressure continues to increase the need for effective cost management so that measures can be constantly adapted in response to an ever-changing external environment. (Hopwood, 2009)

In the company's anti-crisis plan, scenarios must be prepared using cost reduction tools, which will be applied in the case of various phases of negative development. In good times, the company has enough time to carry out efficiency analyzes on the basis of which it can evaluate individual tools so the resulting anti-crisis plan is effective. It is important to identify individual activities as cost bearers that are not vital to the main economic activity of the company. There is a difference in a company that had to be completely closed (such as hotels, fitness centers) and a company that could partially open their business (such as restaurants that could deliver food). In the case of a closed

business, all costs that can be reduced or eliminated must be identified. The company must go into a hibernation stage and the responsible financial manager must not miss any costs that can be eliminated. However, the crisis will have a significant impact on the whole economy, as increased unemployment will also reduce the purchasing power of the population, there is a lack of demand for products in the market, so companies in other sectors must respond too to the situation and introduce measures to increase financial stability. Identifying suitable points where costs can be saved is key. For example, ongoing investments to increase production capacity need to be suspended in a situation where there is uncertain market demand. However, the crisis has also brought opportunities in some sectors for rapid and massive revenue growth. In the case of online stores, for example, companies saw an enormous increase, which was also reflected in increased employment in this segment. Therefore, it is necessary to correctly identify whether it is an investment that makes sense in the current situation or not. The situation needs to be constantly assessed, as it can change from day to day and in the case of new opportunities for revenue growth, it is necessary to respond by investing so that all the potential is used.

Recommendations

Based on the literature review and analysis of the above data, we have developed recommendations for companies from the sectors most affected by the sudden crisis, which should be applied by the managers of the companies concerned in order to avoid a major impact on the company.

1. Managers must first develop an anti-crisis plan, based on analyzes of a specific company and industry, which will take into account the financial situation, the market situation, the organizational structure and the transformation process.

2. Using modern activity-based cost control systems, they must identify the most important activities that are fixed cost generators.

3. Analyze which of these activities can be reorganized, streamlined, limited, or totally eliminated.

4. Reduce inventory and proceed with inventory management Just in time, to reduce the funds tied up in the stock of material.

5. To simplify the organizational structure, at a time of reduced demand, there may be a decrease in the volume of work in individual job positions, which opens up space to assign more work tasks to individual employees.

6. Prefer a flat organizational structure, which is characterized by greater flexibility and will allow the company to respond more quickly to changes in the environment.

7. In uncertain times, enter into short-term employment contracts that allow for quick termination in the event of a sudden change in the environment.

8. Analyze the company's assets and the possibility of replacing ownership of assets with its lease. This measure can immediately increase the company's liquidity, and the cost of renting the property is much lower than the funds that the company raises by selling it. In this case, the short-term effect should be preferred, as the crisis period usually lasts only a few months.

9. Consider outsource activities that are not related to the core business.

Conclusion

The crisis caused by Covid has hit businesses around the world, but each country has its own specificities and therefore the issue cannot be viewed from a global perspective. This article dealt with possible solutions to the effects of the crisis in terms of the authority of the financial manager, who can, with the right and quick decisions, prevent the significant economic damage that the company may suffer. Due to the impossibility of assessing the crisis globally, data from the authors' home country, the Slovak Republic, were used.

We found that the crisis hit companies in the services sector the most, namely the accommodation and food and beverage services sector as we found out on the basis of turnover data. From the employment data in individual sectors, we found that the largest decline occurred in these two sectors, which recorded the largest drop in turnover. It confirms that reducing employees costs is an important tool for reducing costs in times of crisis. The biggest problem in times of crisis is the lack of liquid assets, we found that with a suitable cost management system we can identify activities in the company that the company can temporarily reduce or cancel in order to reduce costs quickly and effectively. We also found that in times of crisis, companies are trying to address this lack of liquidity by delaying the repayment of liabilities, as evidenced by data on the number of requests to defer loan repayments.

The Opportunities and Challenges for Digital Transformation in Egypt

Sherif KAMEL

The American University in Cairo, Cairo, Egypt
skamel@aucegypt.edu

Abstract

Emerging and innovative information and communication technologies have been gradually transforming societies for decades. The impact on individuals and organizations have been immense, especially in emerging markets, offering a solid prospect to make them more agile and competitive and enabling them a platform for economic growth and prosperity. This article demonstrates the opportunities and challenges enabled through innovative technologies in Egypt, emphasizing the developments that took place during the Covid-19 pandemic and its repercussions that led to the acceleration of digital transformation across different businesses, industries, and society. Furthermore, the article highlights the importance of establishing a nationwide entrepreneurial ecosystem that promotes a tech-startup culture that can effectively transform the economy by enabling inclusion, universal connectivity, re-skilling, and up-skilling human capital and a conducive environment to support creativity, innovation, and discovery.

Keywords: Innovation, Entrepreneurship, Digital Transformation, Shared Economy, Emerging Economies, Egypt.

Introduction

Through its ancient history that extends over 5000 years, Egypt has witnessed massive information flows from the Rosetta stone and papyrus papers to the establishment of the Library of Alexandrina. During the middle ages, Arabic manuscripts became one of the most common means of information dissemination. In the early 19th century, Egypt witnessed the publishing of the first journal and the establishment of the first national archive system (Kamel, 1998a). However, until 1985, Egypt was perceived as rich in data but poor in information. Within the government and the private sector, computers were viewed as ends and not means. In addition, accumulated bureaucracy through red tape were coupled with islands of innovation with no connecting bridges restrained information production (Kamel, 1998b). All represented opportunities for development that could help transform the economy with its diversified nature and untapped potentials.

Today, more than ever, information and communication technologies (ICTs) are transforming societies around the world into becoming more competitive, agile, dynamic, and able to adopt different models that allow them to compete both locally and globally using a variety of value chains. The continuous emergence of ICTs has changed how people think, work, study, shop, communicate, get entertained, and in many ways, live. Consequently, these technologies offer an invaluable vehicle for business and socioeconomic development and growth (Allan, 2020; Kamel and Rizk, 2019). Egypt, as an emerging economy, has strived to achieve the potentials of ICT since the 1960s and has continuously been investing in building and upgrading its infostructure and infrastructure to reposition the country as a strategic stakeholder in the endlessly changing regional and global marketplaces (Petrazzini, and Harindranath, 1996). Besides, with the growing and impactful influence of the millennials and their tech-savvy, passionate, connected, and engaged generation, the prospects of digital transformation and consequently the impact on the economy in specific and the society at large continues to represent an invaluable opportunity for Egypt (Rizk and Kamel, 2013).

In the early days of introducing computing to Egypt, the government and the private sector focus was on technical issues and not on decision outcomes; multi-sector coordination was poor, and synergy between information and socioeconomic development strategies was lacking. Given how important and useful ICTs have proven to be to socioeconomic development, especially for emerging markets, Egypt included, building the necessary information infrastructure was a necessity, and innovative tools and applications presented an excellent opportunity for inclusion and equality as well as to improve the lives and livelihoods of the society (Kamel, 2020a).

Building the ICT Infrastructure

Since the early 1980s, Egypt has heavily invested in its technology infrastructure and national infostructure to become a platform and an enabler for the economy's development and growth. An evolving process by design that is iterative and regularly changing to be able to keep pace with the continuous developments and changes taking place in various technology applications and platforms, including relatively more recently the evolution of the fourth industrial revolution and the prospects enabled through the power and reach of artificial intelligence, the Internet of Things, data analytics, drones, blockchains, cloud computing, and robotics to mention a few (Schwab, 2018; Faixó, 2018; Schwab, 2016).

Four decades ago, Egypt launched a nationwide strategy towards its socioeconomic developmental objectives to address different challenges such as debt, a high illiteracy rate, inadequate infrastructure, and structural reform. Over the years, the strategy was amended and adjusted several times to accommodate the changes taking place locally and globally, with ICT continually perceived as a catalyst for the strategy design, development, and implementation (Rizk and Kamel, 2013). Consequently, in 1985, the government of Egypt established the Information and Decision Support Center (IDSC), a think-tank affiliated to the Cabinet of Egypt. The objective was to develop and implement, using a supply-push strategy, large nationwide informatics projects to support socioeconomic development using state-of-the-art ICT (Azab et al., 2009).

The focus on the infostructure was demonstrating the power of information as a factor in manipulating the discourse about socioeconomic reform (Stiglitz, 2002). It is important to note that before the 1980s, the government has dominated the supply of information. However, the number of entities generating information started to expand, and their service quality was improving. Today, social media plays a significant role in that domain as part of the growing global trends in the access and democratization of knowledge (Von Hippel, 2005). During the period 1985-1995, a government-private sector partnership had a remarkable impact on Egypt's infostructure's build-up by establishing hundreds of informatics projects and centers in different public and private sector organizations targeting socioeconomic development and growth. Such projects were considered major building blocks necessary to establish a full-fledged infostructure capable of keeping pace with global sectoral, business, and industry developments.

In 1999, ICT was identified as a priority at the highest policy level, and consequently, a new cabinet office was established; the Ministry of Communication and Information Technology (MCIT). During that period, the ICT sector was perceived as having transformed itself from an industry looking for support and subsidies to an industry contributing tangibly and intangibly to the economy with a total of 5.2 billion U.S. dollars received by the treasury in 2006 through the introduction of a portfolio of telecommunication services including expanding the universal Internet services access across Egypt's different governorates, and other mobile services as well as upgrading the infrastructure of the fixed-line (Ismail et al., 2018).

These technologies offered the global community endless opportunities for job creation, economic development, growth, communication, and collaboration irrespective of time and distance barriers signaling with the invention of both the Internet and mobility, the early signs of acceleration, and digital transformation (Allan, 2020; Friedman, 2016). These technologies have also been a source of regular disruption that prompted innovation, creativity, and discovery and massive implications on society (Kane et al, 2014). Accordingly, since the 1980s, disruption in the way societies operate has been coming in different shapes and forms but predominantly affected by the power and opportunities enabled by these emerging innovative technologies. However, when people talked about disruption, they usually meant the impact that information and communications technologies had on individuals, organizations, and society (Kamel, 2020a).

The Age of Disruption

Since November 2019, the world has been hit with a perfect storm in the form of a disruptive pandemic that has affected both developed and emerging economies alike with no discrimination. The disruption caused by Covid-19 was invisible and resembled a stealth attack. It started in Wuhan, China, and in no time, it spread all over the world. The pandemic has caused a global shock that has led to a slowdown in economies, affected financial markets, and disrupted supply and value chains, requiring immediate worldwide coordination and the development of collective measures to combat it. Meanwhile, the precautionary health and safety measures, including physical distancing and the economic repercussions, have led to millions around the world being forced to work remotely or losing their jobs. The rapid change in how society operates led people to observe the changes that the pandemic has caused in a few months compared to the efforts conducted and the accomplishments realized by chief information and technology officers, experts and professionals in the ICT industry for decades.

It is worth noting that before the pandemic hit, globally, the world was living in an age of pervasive and unprecedented uncertainty. However, it is nothing compared to what we have seen since the outbreak of the pandemic. The current disruption is impacting societies around the world politically, economically, and socially. It is still too early to tell, but the world will most probably witness a U-shaped recession with a potential recovery that will take around one and a half to two years –pending the availability of a timely, tested, affordable, and globally accessible vaccine– and that will hopefully be followed by an upswing in the global economy, which will vary from one country to another. In the meantime, countries are being hit by multiple rapid developments, including falling oil prices, disruptions to trade, volatile stock markets, and severe hits to businesses have forced governments to pass comprehensive and extraordinary policies aimed at stimulating their economies and preventing mass layoffs and business shutdowns, especially among small and medium-sized enterprises (SMEs).

Is Egypt ready to be digitally transformed?

There is nothing remotely good about societies being affected by a pandemic, the magnitude of which has rallied countries around the world to coordinate their efforts to work against a common enemy. However, can the coronavirus have some collateral positives? Are there opportunities that can be created through digital transformation? Is it an opportunity to autocorrect? How can an innovative and entrepreneurial tech-startup contribute to the development of the society of the future? What are the human capital requirements needed as an integral element in developing a nationwide entrepreneurial ecosystem that can transform the economy? What skillsets are required to enable the community to be ready for a digital society connected and driven by innovation and creativity?

These are so many questions with no answers that address how the future will look like, especially with the acceleration of digital transformation over the last decade and more so since the outbreak of Covid-19. One thing that became clear is that people can change; they can adapt if given limited alternatives. For starters, it became evident that the current crisis is already forcing people around the world to adapt and use different technology platforms much more than ever before, even the ones that they are not used to (Sharma, 2020; Faixó, 2018). Furthermore, the merger of infotech and biotech is proving that there are no boundaries to the prospects for what lies ahead and that it will take a brand-new leadership style across different economic sectors as well as innovative approaches to navigate the emerging realities of the fourth industrial revolution, become more resilient, agile and competitive in a continuously changing global marketplace (Sharma, 2020; Kazim, 2019).

When it comes to Egypt, the recent developments since the pandemic outbreak have demonstrated the importance of assessing its ability to adopt digital transformation in government practices, business transactions, and across society to mitigate the impact of disruptions such as that caused by Covid-19 (Wamda and Arabnet, 2020). Consequently, developing and regularly enhancing the required infostructure and infrastructure to support and enable digital transformation in Egypt will be indispensable for individuals, organizations, and societies and more importantly for the second tier of economic reforms following the ones that were successfully implemented during the period 2016-2019 (Kamel, 2020b). This will allow them to stay relevant, competitive, and agile, as well as support society by remaining healthy and surviving the repercussions for the economy and staying safe and thriving in a post-pandemic world.

The disruption caused by the pandemic should push Egypt collectively as a nation –including the government as an enabler, the private sector as a driver, and the civil society as a supporter– to further coordinate its efforts and to think more creatively and ambitiously (Kamel, 2020a). This could include intensifying investments in infrastructure, such as education, healthcare, pharmaceuticals, and ICT, and upskilling the technology-related capacities of one of the country's most precious assets, its human capital, to meet the requirements of digital transformation. This would, in turn, help to accelerate the development of several key sectors such as agriculture, manufacturing, financial inclusion, trade, retail, transportation, and logistics, to mention a few, all of which have enormous potential to thrive (Kamel, 2020c). There is also an urgent need to support micro-enterprises and SMEs and integrate the informal sector into the economy (Kamel and Abou Seif, 2015). As society moves forward while visualizing and projecting the new normal, the policies formulated the and decisions taken should be thoughtful and purpose-driven to support a more robust and competitive private sector, improved productivity, resilient businesses and industries, and a digitally driven government.

It is worth noting that before the pandemic hit, Egypt was on the right track and was doing well from an economic perspective. Economic growth was at 5.6 percent during the fiscal year 2018/2019 and was projected to reach 6 percent in 2019/2020. The economy was among the best performing in emerging markets, and the macroeconomic indicators were all heading in a positive direction following a series of macroeconomic and structural reforms. Despite the pandemic's impact, Egypt is the only economy in the Middle East that showed positive growth during the fiscal year 2019/2020, reaching 3.6 percent. The government is determined to continue its progress in accelerating structural

reforms. On that note, judging by the developments of the first quarter of 2020, digital transformation could play a significant role in the government's future reform plans as it navigates the current crisis while keeping an eye on launching another wave of reforms that would not only build on the hard-won macroeconomic stability achieved over the past few years but also address the longstanding impediments to a competitive private sector-led economic transformation (Morgan, 2019).

Consequently, the next reforms should focus on reducing bureaucracy, red tape, and non-tariff barriers; making finance more accessible; and facilitating private sector access to critical economic building blocks; all can benefit from a well-thought and well-integrated digital transformation strategy and execution. Such access will allow the private sector to expand given the diversified nature of Egypt's economy, which could also lead to more job opportunities, inclusion, economic development, and growth that could improve society's prosperity and reduce poverty levels.

It is worth noting that Egypt's population is growing at an annual rate of 1.9 percent or over 2 million people, and technology access has been rapidly increasing across the country, with 59 percent and 99 percent internet and mobile penetration rates including 39.5 million people who are smartphone users. No less than 60 percent of the population is under the age of 30, reflecting a young society in a nation that is home to more than 100 million citizens. Both elements provide a unique opening for change and improvement. With its energy, ambition, and passion, the intersection of youth with innovation, technology dissemination, and utilization, and a growing interest in self-employment could help create a platform for a tech-based and tech-enabled entrepreneurial space. Furthermore, the universal access to ICT across Egypt's 27 governorates could be an influential contributor and enabler for digital transformation by providing unlimited access to knowledge, opportunities, ideas, and the world at large for Egyptians, regardless of time differences distance.

The Prospects of Digital transformation for Egypt

Digital transformation offers ample opportunities for Egypt. However, innovation in general, and ICT in particular, cannot solve all the problems or answer all the economic and societal challenges that have developed over many decades (Al-Aees, 2019). While digital transformation represents an enabling environment that can make a difference, it should be supported by the required infrastructure and skilled human capital and the proper legal, regulatory, investment, governance, educational, security, and other support environments to an integrated ecosystem. The name of the game is to invest in creating a pool of tech-savvy entrepreneurs and scale-up the number of innovative tech-based and tech-enabled startups through the establishment of incubators across Egypt's universities and higher education institutions. In these incubators, the role of youth, practitioners, academics, industry experts, policymakers, business leaders, mentors, investors, innovators, educators, and trainers can never be discounted (Ismail et al., 2018). It is a collective effort in which everyone should be effectively engaged and empowered.

Digital transformation can help reshape economies and societies and improve their competitiveness by stimulating creativity and innovation, generating greater efficiencies, enhancing various services, and offering a platform for inclusive and sustainable development and growth (Berman and Marshall, 2014; Matt et al., 2015). Accordingly, Egypt has an opportunity to capitalize on digital transformation and realize the goals of its vision 2030 development strategy by (a) unleashing the potential of the private sector; (b) digitizing various government services, which can have the positive effects of facilitating access to services for citizens, improving efficiency, reducing bureaucracy, and assisting the government in combating corruption; and (c) leveraging human capital capacities, with a focus on emerging technologies and investing methodically in building Egypt's innovation capital (Kamel, 2020a). Besides, digitization can offer a seamless platform for customs and tax processes that can remove the impediments facing investors and businesses and help attract more foreign direct investment; the latter has proven relatively difficult to achieve in recent years, especially when compared to pre-2011 levels. It is important to note that while digital transformation will result in many jobs being replaced by machines in the future, new technology-related jobs will be created (Matt et al., 2016). Therefore, policies must be in place to provide sufficient training, human capital development, and social welfare to enable the labor force to embrace and adapt to the continuous changes taking place and have the capacities and skillset to understand and make the most of the prospects enabled through emerging innovative technology platforms.

Building a Startup Ecosystem

The growing crowd of innovative and talented tech entrepreneurs in Egypt could be influential and participate in the country's digital transformation. The following is a sample of promising tech-based and tech-enabled startups that address critical issues of primary importance to society, such as transportation, financial technology (fintech), healthcare, logistics, and distribution.

In transportation, Swvl –established in 2017 and known as the Uber of buses– is a premium alternative to public transport in Egypt. Through a mobile app, customers can book fixed-rate and affordable bus rides on existing routes; this is an effective solution that is much needed, given the traffic and transportation challenges in Egypt's major cities. Swvl is now operating in Egypt, Kenya, and Pakistan.

In fintech, Paymob is an electronic payment enabler established in 2013 that offers integrated infrastructure solutions empowering the masses with instruments that increase financial inclusion, which can be a crucial pillar of economic growth. Fintech can help SMEs –which make up around 80 percent of the country's firms– bridge financial inclusion gaps, move into the formal economy, and effectively improve their capacity to grow and compete. In Egypt, cash is king and therefore represents one of the most attractive markets for fintech. The population's size– which includes a substantial unbanked segment, with no more than 15 percent of the adult population having a bank account, one of the lowest penetration rates in the world– demonstrates the growth potential. Fintech started growing in Egypt in 2008, providing solutions including electronic payments for peer-to-peer transfers and bills, payroll, and pension and social security payments; merchant and online purchases; and the proliferation of smart wallets (Abdel Meguid, 2020). Moreover, fintech can offer the unbanked segment valuable social services such as paying back their loans and transferring money through kiosks across the country. It is expected that Covid-19 will accelerate the move toward mobile services, which will have positive implications, including gradually integrating large segments of the informal economy.

In healthcare, Vezeeta, launched in 2012, is a digital booking and practice management platform for physicians, clinics, and hospitals in the Middle East and North Africa region. In logistics, MaxAB, established in 2018, is an e-commerce wholesale food and grocery marketplace using data-driven technologies and innovative supply chains to serve its customers best. Finally, in distribution, Brimore, established in 2017, is a social commerce and parallel distribution platform that allows local suppliers to have nationwide coverage through a network of individual distributors, mainly housewives, selling products in their circles using omnichannel.

Egypt is a consumer of imported digital products and services and an exporter of digital services, recording total exports of 3.67 billion U.S. dollars in FY2018/19. However, post-pandemic, there will be a clear opportunity to reap the digital dividends and increase the contribution and expand the sector's role with concerted, coordinated actions by society at large, including the government, the private sector, and individuals. Innovative technologies are driving digital transformation and opening a broad spectrum of inclusive development opportunities that narrow the divide between the haves and the have nots (Kamel, 2020a; Matt et al., 2016).

The biggest challenge for digital transformation in general and fintech is indeed culture. There are other challenges, including the unclear legal and regulatory environment, interoperability issues among different systems, and the minimal understanding among many entrepreneurs of the advantages of digital financial services (Abdel Meguid, 2020). Realizing the value of financial inclusion for socioeconomic development and growth, multiple government and private sector institutions are taking steps to help the financial sector advance and overcome these challenges. There are many recently introduced initiatives and projects that support the digital transformation of financial services through increasing access to the required technological infrastructure, encouraging the development and use of innovative digital financial solutions, and increasing awareness of the benefits of fintech, among other digital platforms. Given the size of the population, the prospects are great to transform Egypt into a cashless economy, migrate many of the informal sector transactions to the formal economy, reduce unemployment and poverty levels, and offer various financing options for micro, small and medium-sized enterprises.

Furthermore, there is no doubt that people's habits, attitudes, and behaviors will change as well. There are already early signs of a general shift to digital platforms by both individuals and businesses. Since the outbreak of Covid-19, Egyptians have been using digital platforms to work, study, and shop like never before, and this trend is expected to gain momentum in the future. During the period April-August 2020, statistics from Egypt's National Telecommunications Regulatory Authority (NTRA) show a significant surge in internet usage, including 87 percent and 18 percent increases in-home and mobile internet consumption, respectively. This is in addition to a 131 percent rise in web browsing and significant growth in the use of mobile applications, with a 376 percent increase in accessing educational portals and websites. On this note, the government has already signaled that it will continue to invest heavily in ICT infrastructure to accommodate the proliferation in digital transformation and help stimulate the economy, including the volume of investments in Internet speed– which is expected to increase to 40 Mbps– which have reached 1.6 billion U.S. dollars. Besides, the government targets increasing Internet access for both mobile and fixed Internet to 75 percent of the population. The ICT sector is a growing contributor to Egypt's economy, accounting for 4 percent of GDP in FY2018/19, an increase of 14.3 percent from FY2017/18 (Kamel, 2020a).

The impact of digital transformation is intended to go beyond connectivity to include economic empowerment and growth while also increasing competitiveness (Berman and Marshall, 2014). This consists of the digital transformation of services through a state-of-the-art infrastructure supported by a robust legislative framework that enables electronic commerce, proper governance, data security, and buyer and seller rights preservation. For example, some of the initial digitally transformed services nationwide will include notarizations, driving license renewals, and utility payments. The services will be available through various channels, including the government portal and a portfolio of mobile applications. Furthermore, Egypt Post can take advantage of the trust it has built up in society for more than 150+ years, coupled with its proximity to citizens across the country through its 4,000 premises, to support micro-enterprises and SMEs by offering a variety of digital services. Other digital services in the pipeline include (a) a comprehensive health insurance system; (b) a farmers' card to ensure the delivery of subsidies to their rightful beneficiaries, verify land acquisitions and cultivated areas to develop an integrated agricultural map, help measure the amount of water needed for agriculture, and clarify the gaps between production and consumption; and (c) a restructuring of the national tax system aiming to achieve justice and order.

Conclusion

The role of innovative technologies undoubtedly impacts society, making it more accessible, knowledgeable, agile, resilient, and competitive. This article attempted to share Egypt's experience in building its infrastructure and infostructure as a building block for digital transformation. It emphasized the importance of a well-established, innovation-driven, government-enabled, and private sector-led digital transformation strategy in realizing inclusive economic development and sustainability.

Vision of The Internet of Everything in Everyday Human Existence

Leszek Kiełtyka

Czestochowa University of Technology, Management Faculty, Poland

leszek.kieltyka@pcz.pl

Abstract

The Internet of Things is a natural consequence of technological development and evolution towards automation of processes that do not require human participation, processes which are indispensable for the functioning of contemporary world or contribute to relieving human beings form their duties. The growing technological capacities result in a constant growth of the area where the concept of the Internet of Things can be applied. This occurs through installation of sensors that enable data transfer in a great number of areas. Information maximisation leads to simplified decision-making process. The final customer will be provided to the receiver (e.g. smartphone) specific, resulting information, which will allow for making effective, on-the-spot decisions. Presently, the number of devices that communicate with the use of the Internet in order to gather data, process particular functions as well as supporting man in implementing particular social or business processes is tremendous. This concerns in particular the basic areas of everyday human life (Kryśkiewicz, 2016).
The research goal of the paper is to present the awareness and expectations regarding application of the Internet of Everything in two selected groups of people coming from different countries and continents. The research tool constituted a survey and survey questionnaires. The research was conducted between January and April 2019 using direct interviews and correspondence. The survey was conducted on two groups including several hundred people, which are characterised by a similar working profile and living in Poland and Kenya. The persons who expressed their consent to participate in the research live and work in Czestochowa and Nairobis.

Keywords: IoT, IoE, ICT, process automation.

Introduction

It depends on us whether we will be able to benefit from the blessing of communication technology that is being implemented, among other things, based on the concept of the Internet of Things (objects), Internet of Everything or Industrial Internet of Things. The Internet is no longer limited to computers that allow humans to exchange information. Now it includes devices that until recently were not related by any means to information exchange. In a number of cases these are devices or systems linked with the current functioning of human life. this situation provides abundant possibilities of creating so called "information world", which utilises technology to communicate not only among people but also among people and objects or objects themselves. This is how the so-called Internet of Everything (IoE) is being developed, which is a term that defines a network of humans, processes, data and things connected to the Internet. This term originated initially at CISCO. Also, a counter has been created that summarises the approximate number of the elements of the Internet of Everything. It has been estimated that in 2020 there will be from 25 billion to 50 billion of devices connected the network. In 2019 the value of the IoT market is estimated to amount to USD 1.3 trillion (Kotowski, 2015).

The Internet of Things is a natural consequence of technological development and striving to automate processes that do not require human participation, processes that are indispensable for the functioning of the contemporary world or contribute to reducing the human burden. Growing technological capabilities result in a constant development of the area where the concept of the Internet of Things can be applied (Ghosh, 2015). This occurs through installation of sensors that enable data transmission in a wide range of areas. Information maximisation leads to a simplified decision-making process. Final customers will receive on their receiver (e.g. a smartphone) specific resulting information, which will allow for making effective, ad-hoc decisions.

Cite this Article as: Leszek Kiełtyka " Vision of The Internet of Everything in Everyday Human Existence" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Presently, the number of devices that communicate using the Internet in order to collect data, processing particular functions, as well as assist humans in performing particular social or business processes is tremendous. This concerns in particular basic areas of everyday human life (Kryśkiewicz, 2016).

The research goal of the present paper is to present the awareness and expectations regarding the utilisation the Internet of Everything of two different groups of people from different countries and continents. The survey was conducted on two groups, including several hundred people each, characterised by a similar working profile and living in Poland and Kenya. The persons who accepted the invitation to participate in the survey dwell and operate in Czestochowa (former capital of the province) and the richest district of Kenya's capital – Nairobi.

Motivation to Research Regarding the IoT

Currently, the most exposed area where the information and informatic technologies are being applied is the Internet of Things (IoT) and the Internet of Everything (IoE). The Internet of Everything as it is presently perceived has not been born upon a single ingenious idea. This is an arbitrary set, which utilises electronic and digital forms of communication that have been developing over a longer period of time. The IoT makes use of the existent and developing communication technologies. It utilises the technology of savings and reliability, especially for the operations of data gathering, transfer and security, which are embedded in the utilised system. It also uses data gathered in cloud computing, ICT technologies, software agent technology (Kiełtyka, Niedbał, 2013), semantic networks technology, multimedia techniques and technologies (Kiełtyka, 2009, 2017), virtual technology of organising operations (Kierzkowski, 2013), etc.

Contrary to the adopted name the Internet of Everything (IoE) is not the Internet of „all things", but a set of more or less structured data utilised during a particular communication (Born, 2018). But for the data, which constitutes the primary product for the IoE, it would simply be a generator of electro-waste. The Internet of Everything is not what it seems at first sight. A giant anthill of smart-objects and sensors that communicate one with another, having had a closer look at them turn out to be primarily a world of drastically new data (Kiełtyka, Zygoń (2018).

Regardless of the fact whether we as homo sapiens like the dynamic development of this technology or not, we are unable to oversee it and not utilising it will lead to a gradual alienation from the information society. Therefore, the author of the present paper, having proper access to a relatively numerous population of persons working in distant countries (Poland and Kenya), and employed in similar areas of professional activities, conducted a research that comprised a general analysis of use and awareness regarding the application of solutions related to the vision of the Internet of Everything development.

The applied research methods included surveys and survey questionnaires. The research was conducted between January and April 2019 with the use of direct meetings and correspondence.

Discussion Regarding Research Results

The research results have been presented, among others, in the form of charts that analyse the responses, suggestions and explanations of the survey respondents, who addressed 38 issues presented in the form of questions and selection of options related to the application of the IoT. Conclusions have been drawn from all the issues and situational actions have been described. The underlying objective of the paper was to present the basic factors and forms of communication between the elements of "things" and "all things" and the environment, human beings present in this environment in particular, with regard to their operation, with a special stress on a possibility of utilising them in ecosystems. The selected situational solutions shall allow the readers to familiarise with the possibility of choosing basic, commonly used products, which applied in ecosystem structures are supposed to improve their everyday life (Kiełtyka, 2019). The surveyed groups in both countries included approximately 180 persons each. It should be mentioned here that they were concentrated in enclaves of over 200 thousand of inhabitants. The anonymous responses of the survey respondents were dominated by such professional groups as: managers of various professions, teachers of primary and secondary schools with a small share of academic teachers, healthcare employees – nurses, and a large part of persons who did not specify their profession. Out of the issues that were supposed to be addressed unambiguously by the respondents the author present in the paper five, in his opinion most important areas related to knowledge and application of the Internet of Things and the Internet of Everything.
However, first the author has conducted a brief analysis aimed to compare the level of "digital saturation" in both compared countries. The analysis has shown that in Poland in 2019 at least one computer at home was owned by 83.1% of households with at least one person aged 16–74 years old. Internet access in 2019 could boast 86.7% of

households and this was up by 2.5% than a year before. Within one year the share of households accessing the Internet through broadband connection increased by 4%. Both the type of internet access as well as type of owned connection was diversified with regard to the type of household, place of residence and urbanisation level. Internet access was more frequently owned by households with children than the ones without them. The share of household with internet access was higher in cities than in the country. It was the highest in highly-urbanised areas. The same was true for utilisation broadband Internet connections (www 1).

In case of Kenya the statistics can be at times misleading. According to the Statista portal in 2019 it was estimated that the number of Internet users in Kenya was 46,870,422 people, which corresponded to a penetration rate of 89.7%. In 2019 there were 72 licensed ISPs of which about half were operational. Currently the Communications Commission of Kenya (CCK) is considering conducting a comprehensive Internet Usage Study to confirm the latest number of users in Kenya (www 2).

At the same time the result of another study show that Kenyans have much less access to ICT services than it was previously claimed. According to the report by the Kenya National Bureau of Statistics (KNBS) the number of mobile users stands at 20 million, with the majority of them being women. At the same time, just 20% of Kenyans have access to the internet and only 3.7% of the country's population engages in e-commerce. Only 22.6% of individuals aged 3 years and above used the internet while 10.4% used a computer (www 3).

As one can conclude based on the presented analysis Poland is the country which can boast much more developed digital infrastructure, both related to the number of computers as well as the share of the population that access the Internet using broadband connections. In a way the observed differences regarding the internet infrastructure in both compared countries make the analysis pertaining to the application of the Internet of Everything in both environments even more interesting. This analysis can present what other studies might lack, how important is the IoE for a digitally well-developed country and the one where the internet infrastructure is still at a relatively low level.

Figure 1 presents an analysis of the responses of the survey participants to the question: Have you been familiar with the terms the Internet of Things/Everything before filling in the questionnaire?

Fig. 1: Answers of the respondents to the question: Have you been familiar with the terms the Internet of Things/Everything before filling in the questionnaire?

Source: own elaboration

The received answers allow for drawing the following conclusions:

- the surveyed group of persons from Kenya definitely knows the terms the IoT and IoE,
- poor knowledge of the terms the IoT and IoE was demonstrated by the Polish group of respondents.

In the opinion of the author the situation in the period of conducting the survey may be explained by the fact that since 1989 and the transition towards the market economy Poles in very short time intervals gained access to modern information technologies and techniques applied or introduced in the member states of the European Union (Kiełtyka, 2011). So, a systematic influx of modern communication forms to the Polish market has resulted in a less dynamic interest in introduction of new communication forms, in this case the solutions of the IoT and IoE than in the countries that were previously deprived of such a possibility. The young generation of Kenyan respondents lacked an opportunity to use on a large scale communication technologies that had been developed

and introduced in stages in the developed countries. Presently, their interests have focused on the latest achievements of communication technologies, which include, among others, the technologies utilised in application of the IoT and IoE.

Figure 2 presents a chart, which in a percentage grasp illustrates answers of the respondents to the question: Are you in favour of applying the IoT and IoE in various areas of your life functioning?

Fig. 2: Answers of the respondents to the question: Are you in favour of applying the IoT and IoE in various areas of your life functioning?

Source: own elaboration

It can be observed that the consequence of the analysis of answers presented in Figure 1 is continuation of the presented in Figure 2 responses of the survey participants. The orientation of the Kenyan respondents to utilise the latest communication technologies results from the lack of the burden resulting from the application of previous communication forms. While analysing the responses of the Polish survey participants one may notice that generally in the human nature there is no will the eliminate the previously purchased objects that proved to be reliable. To do so, a strong economic stimulus or a necessity of change driven by the nature of undertaken work must occur. Therefore, the chart in Figure 2 illustrates very clearly the influence of new forms of communication on the expectations and necessity to apply solutions that provide for a possibility to utilise the IoT and IoE in the lives of the survey respondents.

In Figure 3 the author present the chart illustrating the respondent answers to the question: Is the utilisation of products and services that use the concept of the IoT and IoE your own decision or rather a necessity?

While analysing the charts in Figure 3 one can draw a general conclusion that regardless of the fact whether the survey respondents have had access to communication technologies and techniques in a longer or shorter time period, presently both the necessity as well as free will to utilise the concept of the IoT and IoE are high and similar. The distribution of the remaining answers confirms the conclusions drawn while analysing Figure 1. In case of the Polish respondents the necessity to utilise the IoE is over twice lower. The Kenyan respondents in turn demonstrate over five times higher necessity to utilise the concept of the IoT and IoE in their existence.

Fig. 3: Answers of the respondents to the question: Is the utilisation of products and services that use the concept of the IoT and IoE your own decision or rather a necessity?

Source: own elaboration

Figure 4 presents the answers of the respondents to the question: Would you like to participate in the proces of testing new solutions related to application of the IoT and IoE?

Fig. 4: Answers of the respondents to the question: Would you like to participate in the proces of testing new solutions related to application of the IoT and IoE?

Source: own elaboration

The conclusions that can be drawn based on this survey question indicate that the Polish respondents demonstrate a moderate interest in the notion of testing the new solutions in the scope of utilising the IoT and IoE. This does not mean that they are less interested than their Kenyan counterparts. While analysing this chart one can have an impression that access to a number of systems of communication, even interpersonal one, which has been made available over a longer period of time results in a lower expansion to utilise the latest telecommunication achievements.

In Figure 5 the author present the chart that illustrates the percentage share of the respondents in the answer to the question: To what extent the development of the IoT and IoE may influence your activeness in the private and professional area?

Fig. 5. Chart of the answers to the question: To what extent the development of the IoT and IoE may influence your activeness in the private and professional area?

Source: own elaboration

Fifty percent of the Kenyan survey respondents declared that the development of the IoE has a critical influence on their professional life. In the private area this influence is ten times lower. The analysis of these answers allows for a statement that for the surveyed group in Kenya utilisation of the solutions applied through the IoT or IoE is too expensive. For the survey respondents in Poland the influence of the IoT and IoE is significant, however, not as critical as in case of the Kenyan respondents. Still, is significantly influences both their professional as well as private area in the proportions respectively 50% and 40%. Such a result may stem from the fact that the surveyed group in Poland is more open to accepting solutions that improve their private and professional lives.

The surveyed groups were also asked questions and presented issues related to application of the IoE where more than one answer was possible. Out of the extensive data that was collected the author will present the most interesting in their opinion issues. One of the questions of the survey was as follows: What areas of the application of the IoT and IoE do you notice or utilise in your everyday life? In both groups the answers to this questions included mostly the following: home appliances, multimedia equipment, ongoing analysis of physical activeness, health – through monitoring physical effort, blood pressure analysis, current calorie consumption and sleep analysis. In addition, the Polish group of the respondents attached significant importance to: environment monitoring, smart network application (remote meters of water, electricity, gas consumption), issues related to smart buildings, residential districts, housing estates, municipalities and towns. The surveyed group of Kenyan respondents attached great importance to: trade and marketing (monitoring customers, customer segmentation) analysis of plant breeding, infrastructure management (integrated rescue systems, toll systems), automation (automated logistic processes, automated factories and work posts, unmanned vehicles). However, this group cannot be identified as representatives of Kenya or even Nairobi. As it has been already mentioned that surveyed group included the inhabitants of the richest district in Nairobi.

For the issue regarding the level of benefits resulting from the utilisation of the IoT and IoE the convergence of the respondents' answers concerned: development of self-diagnostics of machines and devices, improved monitoring and control of processes and facilities, more common access to information, relatively fast change of lifestyle and higher level of healthcare for the respondents and their families.

The survey respondents from Kenya have also included into the group of benefits of IoE application the following: increased employee productivity, a possibility of country's faster development, better control over devices and processes. In the surveyed group in Poland, apart from the abovemetioned common benefits, its members emphasised: time saving, reduced energy consumption, increased employee safety, better purchase planning and stronger integration between the virtual and real world.

Another issue concerned the level of threats that may occur while utilising the IoT and IoE. Both groups of the respondents almost unanimously stated that: humans are becoming increasingly dependent on the informatic equipment, aggressive advertising sent to individual e-mail address is being used too extensively, there is a growing feeling of threats caused by hackers, probability of infringement to privacy is on the increase, a growing invigilation of people can also be observed through the use of their portable devices (smartwatch, smartband, smartphone, iPhone). The survey respondents from Kenya also pointed out to a possibility of exerting pressure on persons and organisations by global corporations and a possibility of taking unauthorised control over the devices. The Polish survey respondents also emphasised a possibility of confidential data leak occurrence, which concerns them and their relatives, as well as using unmanned objects, for example, terrorist attacks. A number of other threats were also signalled by some of the surveyed.

limitation of the IoT and IoE Application

While discussing the application of the IoT and IoE several significant factors shall be taken into consideration. First of all the ongoing miniaturisation which enables incorporating microcontrollers in virtually all devices and objects. Microcontrollers are designed to cooperate directly with various external devices, including ones the control of which would require the traditional microprocessor to use additional peripherals (Xia, 2012). Another issue of key importance is the development of mobile communication technology (wireless in particular) which would make common utilisation of communication among devices and objects impossible, especially the area of everyday human life (HBR Polska, 2015).

The significant limitations include the following:

- power supply problem. Despite being equipped with ever more powerful batteries the devices will sooner or later require to be plugged into electric charging systems or replaced with new ones. Although ever more advanced technologies of wireless energy acquisition are being utilised, the scope of their dissemination is not satisfactory.
- optimum miniaturisation. The shape and form should allow to incorporate sensors in virtually all devices and objects.
- technical infrastructure. It translates into a limited number of IP addresses. A solution to this problem is the protocol in the sixth version which introduces the IPy6 standard.
- lack of uniform standards. They concern in particular data security, as well as privacy (Krejtz, 2015).
- personal data security. This human factor may constitute a serious obstacle for the dissemination of the assumptions of the IoT and IoE concept.
- data availability. The issue of communication that utilises the Internet results in a feeling of being threatened by entities or persons potentially interested in intercepting data.
- human conviction of being absolutely secure. Documenting that application of technology for communication between objects and computer devices is secure and desirable.

The world of technology is facing a great challenge. Security needs to be ensured and people need to be persuaded that information that is incessantly collected by devices, i s protected. Considering the business potential of the IoT utilisation one can expect that this problem will be solved. Although this goal cannot be easily achieved, it can be accomplished, the example of which may be banks and virtual currency. Nowadays it is rare for people to wonder whether their resources in the bank account are protected. If the data transmitted among devices is secured similarly and the technology develops, the IoE will become reality (Porter i in., 2015).

Conclusions

Things, systems, objects, structures, elements operated based on ecosystems are equipped with sensors that facilitate contact with the environment, which can be used in a free and unlimited manner by every person (Kiełtyka, 2019). In the present paper its author also attempted to present an outline of applying the Internet of Things and Internet of Everything concept in potential areas of its utility. The presented analyses of the opinions of survey participants provide insights regarding the awareness of developing interactions with things and through things with communication systems.

Based on the responses of the survey participants one can conclude that the IoT and IoE make it necessary to abandon the previous practices where the prediction model was built based on the collected data and then applied in operations as long as it retained required qualitative parameters. Tools should ensure effortless integration of new data and incorporating it into the analyses.

The conclusions that have been drawn allow to recognise the intensity of human utilisation of contemporary communication technologies, depending on commonly introduced to the given country's market, consumer electronics devices. Similar research conducted in other countries will allow for creation of a utility map regarding the devices that make use of the IoE and retrofitting these areas with proper informatic tools.

The presented brief analysis of two groups of various social structure and relatively homogenous professions, whose representatives participated in the conducted survey, one can state that humans strive for the existence that will allow them to contact the world, and most importantly one another, without any interference.

It needs to be stressed that the surveyed group of Kenyan respondents does not reflect the intellectual potential of even a minimum part of its inhabitants. The group of persons from Nairobi, dwelling in the richest district of the Kenyan capital, were mostly employed to provide widely understood services at the modern airport near Nairobi. Therefore, the paper analyses the vision of utilising the IoT and IoE in everyday life of these persons. The Polish group of respondents in turn may be treated as representatives of a vast majority of Polish citizens.

Abstract

The classical models for construction of investment portfolio takes into account only two criteria for assessing investment opportunities: expected return and risk measured with a variance This approach can be criticized for several reasons. Firstly, it takes into account only information that is revealed in the market prices of the stock. However a more detailed analysis of the situation of a company, based on some fundamental indicators, can provide more clues about possible risks and opportunities connected with investing in its stocks. Secondly, the variance can be a poor measure of risk in the situation of big jumps in stock prices, when the distribution of returns differs much from the normal distribution. Thirdly, the disadvantage of the variance is that it treats in the same way negative and positive deviations from the expected return. In the paper we consider some extension of classical portfolio theory and try to evaluate them in the situation of the crisis. We consider some additional criteria for portfolio selection, based on the market multiples representing overall situation of companies. Additionally, we consider semi-variance as an alternative measure of risk. We construct a range of portfolios which were build using different criterion for risk and fundamental values of companies from the Polish stock market. Then we compare their returns in the situation of crisis after outburst of Covid-19 pandemic. The results from empirical research for the major companies traded on the Warsaw Stock Exchange reveals that investors can receive better investment results by augmenting standard Markowitz model with an additional criterion connected with a fundamental standing of companies such as book to market or earnings to market. The second result is that using nonclassical risk measures, such as semi-variance instead of variance, gives better results and this method of measuring risk is especially essential in in the period of collapse on the capital market.

Keywords Portfolio Analysis, Fundamental Value, Multicriterial Choice, Market Multiple, Downside Risk.

Introduction

Classical methods for selecting an investment portfolio, developed by Markowitz (1952, 1959) and Sharpe (1963), take into account only the market performance of companies, measured with changes in their prices. In the classical model, potential portfolios of investment are evaluated according to two criteria: expected return (which describes the potential level of profitability from an investment) and risk. The first criterion is measured with the expected rate of return and the second one - with the variance or standard deviation of returns. No other criteria are considered that might give some additional information about the financial standing and prospects of a company that could influence prices of its shares.

In recent years, however, there has been a growing interest in portfolio analysis methods with alternative ways of constructing portfolios. The article by Kolm, Tütüncü and Fabozzi (2014) contains a review of major developments in the portfolio theory since it its origin, and the book by Doumpos and Zopounidis (2014) draws attention to multicriteria methods used in this field. Most innovations depend on using some criteria of risk other than variance or standard deviation of returns, for example semi-variance or conditional value at risk. The article by Fabozzi, Focardi and Jonas (2007) presents a variety of risk measures that are currently used in the practice of portfolio

investments. In other approaches, some characteristics of the distribution of returns on assets are used as additional criteria for evaluating portfolio performance. Examples of such characteristics can be skewness or kurtosis. Expanded portfolio analysis is presented by Briec, Kerstens and Jokund (2007) or Rodríguez, Luque and González (2011).

There are several studies which include criteria not based on returns on assets. There is a branch of the literature which takes into account ethical, social or environmental criteria in portfolio construction, for example the so-called socially responsible investments approach described in Steuer, Qi and Hirschberger (2007). The articles by Ballestero et al. (2012) and Bilbao-Terol et al. (2013) are a few more examples illustrating this approach.

Lo, Petrov and Wierzbicki (2003) considered liquidity of stocks as an additional criterion in the portfolio construction process. There are only a few papers which also take into consideration fundamental values of companies. Xidonas, Mavrotas and Psarras (2010) considered the sum of dividends paid by companies. Jacobs and Levy (2013) took into account the risk associated with leverage. The utility function of an investor includes the costs of margin calls, which can force borrowers to liquidate securities at adverse prices due to their illiquidity, losses exceeding the capital invested, and the possibility of bankruptcy.

In accordance with the theoretical concept and empirical research (Fama and French 1992, 2015, 2017; Lam 2002; Zaremba, Czapkiewicz 2017), fundamental factors are important in shaping returns on capital markets. Therefore, it seems rational to include them in a stock portfolio model. The current extensive research on the main financial markets of Eastern Europe has corroborated significant impact of fundamental information concerning companies on their rates of returns. This has also been found to hold true for the book to market ratio as an indicator of the financial standing of companies. The research sample included five countries: the Czech Republic, Hungary, Poland, Russia, and Turkey (Zaremba, Czapkiewicz 2017).

There have been several attempts to combine a portfolio analysis with the fundamental analysis of companies from the Polish stock markets. Tarczyński (2002) developed a synthetic measure to evaluate the economic and financial standing of a company, which he called the taxonomic measure of attractiveness of investment (TMAI), and to apply this measure as an additional criterion in the evaluation of possible portfolios. The portfolio constructed with the use of TMAI was called a fundamental portfolio. This model has been modified in recent years, for example by substituting variance with semi-variance as a risk measure (Rutkowska-Ziarko and Garsztka 2014). In Rutkowska-Ziarko (2013), the Mahalanobis distance was used to determine the TMAI due to possible correlation between diagnostic financial variables. Another method was proposed by Pośpiech (2019) in the research on financial ratios, and market indicators were applied to guide the initial selection of companies.

In the work apart from the classic measure of risk (variance), we also used semi-variance. The use of the downside risk measure in choosing an investment portfolio seems to be particularly useful in times of strong declines in the financial markets, such as in February and March 2020. They were caused by the decline in investor optimism caused by the development of the Covid-19 pandemic. In the calculation of semi-variance one takes into account only negative deviations below a certain level. Upward deviations, which are connected with returns higher than expected, are not taken into account in determining this measure. The advantage of semi-variance is also that there is no need to make any assumptions about the distribution of rates of return and investor's utility function (Harlow, Rao 1989). The quadratic utility function has some undesirable properties, and therefore misrepresents the actual behavior of investors. First of all, it reaches a maximum for a certain rate of return and then its value decreases with the increase in returns, which is in direct contradiction with the preferences of investors who always prefer to have more than less. Building an effective portfolio for semi-variance is more complicated comparing to the approach that uses variance as a risk measure. It is impossible to use the standard solver software to find a minimum semi-variance portfolio. In the calculations of semi-covariances one has to know in which periods the rate of return of the entire portfolio was lower than the target value and this depends on the composition of the portfolio.

The article is organized as follows. After this introduction, in section 2 we present a brief description of commonly used market multiples and give some reasons why they could be used as an additional criterion for portfolio choice. Section 3 gives a description of downside risk measures. Section 4 contains a mathematical formulation of portfolio optimization problems and about algorithms that was used to solve them. Section 5 presents results of empirical research concerning Polish stock market during the crisis of the Covid-19 pandemic.

Market Multiples

Market multiples provide information on how the market values a publicly traded company. To calculate values of these multiples market data and financial results of a company are used. Breen (1968) and Basu (1977) analyzed the impact of market multiples on future profitability of companies. The results indicate that portfolios formed from companies with lower P/E multiples had a higher annual rate of return in the following year than portfolios formed

from companies with higher P/E multiples. The article of Basu (1977) is frequently claimed to be the first publication which analyze the impact of market multiples on future profitability of companies. However, similar research was conducted even earlier, for instance by William Breen (1968). He investigated companies from index S&P500 in the period from 1953 to 1966, using the COMPUSTAT database. It is a source of fundamental and market information on active and inactive companies and covers about 99% of the world's total market capitalization. For particular years, equally weighted portfolios were formed (with 10 and 50 companies) using shares of companies with the lowest and the highest *P/E* multiple values. The results indicate that portfolios build with the shares of companies with lower *P/E* multiples had higher annual rate of return in the following year than portfolios build using companies with higher P/E multiples.

Barbee, Jeong and Mukherji (2008) investigated the impact of market multiples values on future prices of stocks. They analyzed profitability of equally weighted portfolios created using the shares of companies with various values of particular market multiples.

The most popular indicator of firm evaluation by the market is P/E multiple, which relates earnings per one ordinary share to its market price:

$$P/E = \frac{market\ price\ per\ share}{profit\ per\ share},$$

In the study four different measures of the ability of a company to generate profit were considered. It was net profit (EAT), gross profit (GP) and earnings before interest, taxes, depreciation, and amortization (EBITDA), operating profit (EBIT).

Net profit is the last position in the Profit and Loss Account, it is calculated as follow:

$$EAT = net\ sales - cost\ of\ goods\ sold - operating\ expense - taxes - interest.$$

Gross profit is earnings before taxation. EBITDA is earnings before interest, taxes, depreciation, and amortization. EBITDA can be used to describe a company's financial performance without accounting for its capital structure. Operating profit is an accounting metric measuring the profits that a company generates from its operating activity. The interest and taxes are not considered here.

One can relate a share price not only to various profit categories but also to other characteristics describing the economic situation of the company. It can be important for an investor to relate the market valuation of the company's share capital to the net value of its assets. As for P/BV multiple, the price of one ordinary share is related to the company's book value, estimated per one ordinary share. This multiple outlines the company's market value in relation to its book value:

$$P/BV = \frac{market\ value\ per\ share}{book\ value\ per\ share}$$

where:

$$book\ value\ per\ share = \frac{assets - liabilities}{number\ of\ shares}.$$

This value refers to the total amount a company would be worth if it liquidated its assets and paid back all its liabilities. Book value is also the net asset value of a company.

A positive relationship between book to market ratio and average returns was described by Rosenberg, Reid and Lanstein (1985). This phenomenon was also observed for Japanese stocks (Chan, Hamao, and Lakonishok 1991). Based on this research Fama and French (1992) supposed that book to market would be a important risk factor explaining the variability of stock rate of returns.

In this paper we instead of using classical market multiples we use their reciprocals, i.e. values of financial indicators (expressed per one share) divided by current market price of a share. The reason is the additivity of such indicators. The value of such indicator for the whole portfolio is a weighted average of the values of indicators of individual companies. Thus P/BV is replaced by a book to market ratio (BV/M):

$$BV/M = \frac{book\ value\ of\ the\ company}{market\ value\ of\ the\ company} = \frac{book\ value\ per\ share}{price\ of\ the\ share}.$$

The same was used for P/E multiple – in fact for the whole group of market multiples based on various methods for calculating company's profits. Instead of price to equity earnings to price ratio (E/M) was used, calculated as in equation below:

$$E/M = \frac{profit\ per\ share}{market\ price\ of\ a\ share}.$$

Downside risk in portfolio choice

In the portfolio theory, since its very beginning till the present day, variance has been a commonly used risk measure in capital market analysis (Markowitz 1952). At the same time, for almost so long there were doubts concerning the validity of using this risk measure (Markowitz 1959). The main disadvantage of variance as a risk measure is the fact that it treats in the same way negative and positive deviations from a mean rate of return. In fact, negative deviations are undesirable and positive deviations create a possibility of greater profit. To measure only negative deviations, Markowitz (1959) proposed a semi-variance, which is a mean of deviations below a certain level. The semi-variance and lower partial moments take into account only the variability on the left side of a distribution. The reference point may be the mean as in the case of the variance, but one can also take a different value as a reference point. Using semi-variance as the measure of risk is consistent with the intuitive perception of investors' risk (Boasson, Boasson, Zhou 2011).

Variance is assumed to be an appropriate risk measure when the distribution of returns is normal, or at least symmetric, or when investor has a quadratic utility function. Classical Markowitz's model is ineffective in selecting portfolios that comprise assets with skewed returns (Foo, Eng; 2000). The traditional mean-variance model, which treats deviations above and below target returns equally, tends to overestimate risk and imposes unnecessary conditions that rule out portfolios that are downside efficient.

Pla-Santamaria & Bravo (2013) constructed portfolios of stocks of blue chips companies from Dow Jones Industrial Average. Their results show significant differences between the portfolios obtained by mean-semi-variance efficient frontier model and those portfolios of equal expected returns obtained by classical Markowitz mean-variance efficient frontier model.

An investor who does not wish the return of his portfolio to fail below the target rate of return would tend to compose portfolios minimizing downside risk measures (Klebaner, Landsman, 2017).

It is believed that with symmetrical distributions, variance as a risk measure is no worse than semi-variance (Estrada, Serra, 2005; Galagedera, Brooks, 2007). However research on capital markets shows that the distributions of rates of return of many companies are not normal or at least symmetrical (Adcock, Shutes, 2005; Estrada, Serra 2005; Markowski 2001, Post, van Viet, 2006; Sun Q., Yan 2003). Then the use of lower risk measures becomes important. In the case of right-skewed distributions of returns the main part of the variance is made up of the upper deviations, which mean the achievement of high returns. The impact of lower deviations is relatively small. For this reason, investors are looking for companies with right-skewed distributions of returns (Galagedera, Brooks 2007; Peiro, 1999), which suggests that the issue of skewness cannot be ignored in the risk analysis, even if distribution of returns of some companies are symmetrical. Also, according to the perspective theory (Kahneman, Tversky 1979), it is more appropriate to use semi-variance instead of variance as a risk measure.

The arguments presented before speak in favor of lower risk measures if one compares them with their classic counterparts. Lower risk measures, such as for example a semi-variance, allow for a universal approach to risk analysis and stock portfolio construction, regardless of the empirical distribution of returns; One also does not have to assume a specific analytical form of the utility function. It is sufficient to make an obvious assumption that an investor prefers to gain more than less, and therefore that higher rates of return are better than lower rates of return.

A semi-variance, defined by Markowitz (1959), is a lower counterpart of a variance. This lower risk measure is a sum of squared of lower deviations from the target rate of return γ. It is calculated with the following formula:

$$dS^2(\gamma) = \frac{\sum_{t=1}^{m} d_t{}^2(\gamma)}{m-1}, \quad t = (1,2,\ldots,m),$$

where

$$d_t(\gamma) = \begin{cases} 0 & for\ z_t \geq \gamma \\ z_t - \gamma & for\ z_t < \gamma \end{cases}$$

z_t – rate of return of the company i in the period t

$dS^2(\gamma)$ – a semi-variance for the company i

m - the number of time periods
γ - mean rete of return or any target rate of return chosen by an investor

Extensions of the semi-variance as a risk measure are lower partial moments, introduced by Bawa (1975) and Fishburn (1977). According to these authors the lower partial moment of order n is given by:

$$LPM_i^n = \frac{1}{m-1}\sum_{t=1}^{m} lpm_{it}^n,$$

Where

$$lpm_{it} = \begin{cases} 0 & for\ z_t \geq \gamma \\ z_t - \gamma & for\ \ z_t < \gamma \end{cases}.$$

Notice that for $n = 2$ lower partial moment is equal to semi-variance.

The semi-variance of an investment portfolio $dS_P^2(\gamma)$ is given by:

$$dS_P^2(\gamma) = \sum_{i=1}^{k}\sum_{j=1}^{k} x_i x_j d_{ij}(\gamma)$$

where x_i is the share of the stock i in the portfolio and $d_{ij}(\gamma)$ is the semi-covariance of the rate of return for the *i*-th and the *j*-th share, which is defined by

$$d_{ij}(\gamma) = \frac{1}{m-1}\sum_{t=1}^{m} d_{ijt}(\gamma), \tag{1}$$

where:

$$d_{ijt}(\gamma) = \begin{cases} 0 & for\ z_{pt} \geq \gamma \\ (z_{it} - \gamma)(z_{jt} - \gamma) & for\ z_{pt} < \gamma \end{cases},$$
$$z_{pt} = \sum_{i=1}^{k} x_i z_{it},\ \ t = (1,2,\ldots,m).$$

It should be noted that the semi-variance of a portfolio depends on the assumed rate γ and it should be recalculated with each change of the parameter γ, which depends on the structure of the portfolio.

Problems for portfolio choice

We consider a portfolio of k different assets. Let μ_i be a mean return of an asset i, estimated from the last m observations of:

$$\mu_i = \frac{\sum_{t=1}^{m} z_{it}}{m}.$$

By σ_{ij} we denote a covariance between returns of asset i and that of asset j:

$$\sigma_{ij} = \frac{1}{m-1}\sum_{t=1}^{m}(z_{it} - \mu_i)(z_{jt} - \mu_j).$$

By x_i we denote the proportion of wealth invested in asset i. The mean return of the portfolio is then given by the formula

$$\mu_P = \sum_{i=1}^{k} x_i \mu_i$$

and the variance of portfolio's rate of return is given by

$$S_P^2 = \sum_{i=1}^{k}\sum_{j=1}^{k} x_i x_j \sigma_{ij}.$$

Semi-variance of the portfolio form given by

$$dS_P^2(\gamma) = \sum_{i=1}^{k}\sum_{j=1}^{k} x_i x_j d_{ij}(\gamma),$$

where semi-covariances of assets' returns are given by (1).

We assume that we also consider some market multiple. It can be connected with book to market value per share or with earnings to price ratio of a share. By β_i we denote the value of this criterion for the asset i. The value of this multiple for the whole portfolio is given by

$$\beta_P = \sum_{i=1}^{k} x_i \beta_i.$$

In the empirical part of the work we consider portfolios which are the solutions of the following optimization problems:

a) Portfolio minimizing the variance, i.e. a portfolio than is the solution of

$$\min_{x_1,\dots,x_k} S_P^2 = \sum_{i=1}^{k} \sum_{j=1}^{k} x_i x_j \sigma_{ij} \quad (2)$$

with the restriction that

$$\sum_{i=1}^{k} x_i = 1, \quad (3)$$

$$x_1, x_2, \dots x_k \geq 0. \quad (4)$$

b) Portfolio which minimizes variance with a restriction on mean return. In this case we assume that mean return of portfolio should be no smaller than the required rate of return μ_0. The optimization problem is given by (2)-(4) with an additional restriction

$$\mu_P = \sum_{i=1}^{k} x_i \mu_i \geq \mu_0 \quad (5)$$

c) Portfolio which minimizes variance with a restriction on mean return and on its fundamental value. We assume that fundamental value of a portfolio (measured with one of market multiples) should be no lower than its required value β_0. This gives a problem (2)-(5) with an additional restriction

$$\beta_P = \sum_{i=1}^{k} x_i \beta_i \geq \beta_0 \quad (6)$$

From mathematical point of view problems a-c are problems of quadratic optimization with linear restrictions (given by equations and inequalities). They can be solved using standard algorithms. We have solved them using Goldfarb and Idnani (1983) method implemented in the R package *quadprog*.

The second set of portfolios are those that was optimized with the usage of semi-variance as a measure of risk. The optimization problems were defined as follows.

d) Portfolio minimizing unconditional semi-variance, i.e. a portfolio than is the solution of

$$\min_{x_1,\dots,x_k} dS_P^2(\gamma) = \sum_{i=1}^{k} \sum_{j=1}^{k} x_i x_j d_{ij}(\gamma), \quad (7)$$

with the restrictions (3)-(4).

e) Portfolio minimizing semi-variance with a restriction on mean return, which should be no lower then μ_0. The optimization problem is given by the set of conditions (x6) and (3)-(5).

f) Portfolio which minimizes semi-variance with a restriction on mean return and on its fundamental value. The optimization problem is given by the set of conditions (7) and (3)-(6).

The problems d-f are not standard optimization problems, because semi-covariances $d_{ij}(\gamma)$ in (7) change with the changes in the portfolio structure x_1, …, x_k (which changes mean return γ). Using semi-variance to determine effective portfolios creates considerable problems because in the calculations of semi-covariances $d_{ij}(\gamma)$ one has to know in which periods the rate of return of the entire portfolio was lower than the target value γ, and this depends on the composition of the portfolio. This makes calculations of effective portfolios with semi-variance as a risk measure more complicated than is in the case when variance is used. When a portfolio with the minimum semi-variance is determined, each time the composition of the portfolio or the target `rate of return γ changes. Thus the semi-covariances $d_{ij}(\gamma)$ should be re-estimated.

To solve these problem the following numerical algorithm was used. We have started with some initial portfolio (in this case it was a portfolio minimizing variance). Then we solve each of the problems d-e as a problems of quadratic programming, using Goldfarb and Idnani (1983) method. After each iteration we refreshed a value of γ based on the new solution. Then we re-estimated semi-covariances $d_{ij}(\gamma)$ and solve the problems with the new input data. We repeated this process until convergence, i.e. until changes in portfolio structure between each iterations was sufficiently small. In the calculations we used procedures written in R and the R package quadprog.

Data and Empirical Results

The studies covered 20 largest and most liquid companies listed at Warsaw Stock Exchange excluding financial companies. Close share prices from the period 1.4.2016–4.9.2020 were taken for analysis. In the estimation we considered portfolios assessed by their monthly rate of returns. The parameters (mean returns, variances and semi-variances) used in constructing for the portfolios build in the research were estimated using three years' period before the starting moment of an investment. Figures from financial statement such as: *net profit* (EAT), *gross profit* (GP) and *earnings before interest, taxes, depreciation, and amortization* (EBITDA), *operating profit* (EBIT) and *book value* (BV). They changed with the publication of the companies' quarterly financial statements. We have calculated the appropriate indicators for each company according to its financial statement. For the calculation of financial indicators we always used the latest available data, according to the date of publication. The article uses the financial statements for the period from Q3 2019 to Q2 2020. Information on financial results is usually published with a delay of 60 to 120 calendar days. It was assumed that portfolios purchased on a given day were sold after a month (four weeks). The data has been taken from Thomson Reuters database – Refinitiv Eikon.

In the case of economics, It is not possible to carry out repetitive experiments, as is the case, for example, in physics or chemistry. The article uses the Covid-19 epidemic as a natural experiment. During the epidemic, there was a sharp collapse on the stock exchanges, which allows to test the usefulness of various risk diversification methods in times of sharp drops in prices in financial markets.

In the paper we consider 15 types of portfolios. Table 1 contains descriptions of these types and symbols used to refer to them.

Table 1: The list of kinds of constructed portfolios

Portfolio	Description
Equally weigted	A portfolio with equal share of each asset
MinV	A portfolio minimizing variance (unconditionally)
MinV-E	A portfolio minimizing variance with a restriction on mean return
MinV-E-EBIT	A portfolio minimizing variance with a restriction on mean return and EBIT/M
MinV-E-GP	A portfolio minimizing variance with a restriction on mean return and GP/M
MinV-E-EBITA	A portfolio minimizing variance with a restriction on mean return and EBITDA/M
MinV-E-EAT	A portfolio minimizing variance with a restriction on mean return and EAT/M
MinV-E-B	A portfolio minimizing variance with a restriction on mean return and B/M
MinSV	A portfolio minimizing semi-variance (unconditionally)
MinSV-E	A portfolio minimizing semi-variance with a restriction on mean return
MinSV-E-EBIT	A portfolio minimizing semi-variance with a restriction on mean return and EBIT/M
MinSV-E-GP	A portfolio minimizing semi-variance with a restriction on mean return and GP/M
MinSV-E-EBITA	A portfolio minimizing semi-variance with a restriction on mean return and EBITDA/M
MinSV-E-EAT	A portfolio minimizing semi-variance with a restriction on mean return and EAT/M
MinSV-E-BV	A portfolio minimizing semi-variance with a restriction on mean return and BV/M

We created altogether 2655 portfolios during 177 trading days.

During the research period, four research sub-periods of different length were specified. The division criterion was the changes in the situation on the capital market, which was reflected in the changes in the values of the WIG Index, which is the main index on the Warsaw Stock Exchange. The key aspect for identifying sub-periods was a situation on the market during buying a portfolio and selling it. Table 2 contains descriptions of sub-periods.

Fig. 1: WIG closing price

Table 2: Research periods

The time of buying a portfolio	The situation on the capital market
21.11.2019-29.01.2020	buying and selling before the collapse of the market
30.01.2020-10.03.2020	selling in the collapse of the market
11.03.2020-13.05.2020	buying and selling in the growth of the market
14.05.2020-07.08.2020	buying and selling during stabilization on the market

Due to the very large number of considered portfolios (2655), in the paper we omit the structure of these portfolios and other elements of ex-ante analysis, such as the expected portfolio risk, average rate of return or the average market ratio. All the characteristics of the distribution of return presented in Tables 3-7 refer to realized returns. That is, they describe the actual returns of investors, as well as the risk they bear. For the individual sub-periods and the entire research period, the following were characteristics were calculated: mean rate of return, minimal rate of return, Value-at-Risk (VaR), semi-deviation, standard deviation and skewness.

Table 3: Summary statistics of the realized rates of return for the portfolios bought in the time between 21.11.2019-29.01.2020 – I period (44 trade days), before collapse of the market

In the first research sub-period, the negative effects of the Covid-19 pandemic have not yet affected the Polish stock market. We can observe that all the portfolios minimizing the semi-variance have right-skewed distributions of rates. Returns of equally weighted and portfolios minimizing variance were left-skewed. The highest average rate of return occurs for portfolios minimizing semi-variance and with a fundamental criterion. However, it is difficult to say unequivocally which type of diversification was the most effective in reducing the risk during this period.

Table 4: Summary statistics of the realized rates of return for the portfolios bought in the time between 30.01.2020-10.03.2020 – II period (29 trade days), the collapse of the market

At the end of January 2020, the financial markets collapsed and this situation lasted until mid-March. It affected not only Poland but practically all the most important world exchanges. During this period, all average rates of return were negative. The least effective strategy in this time was to select an equally weighted portfolio. It was the least

profitable and the most risky one, taking into account, among others, VaR 0.1, VaR 0.05 and semi-deviation. It can be seen that the most secure and at the same time the most profitable were the fundamental portfolios that minimize semi-variance. The distributions of realized returns were right-skewed (with only one exception for the portfolio minimizing variance), but the strength of this asymmetry was small.

Table 5: Summary statistics of the realized rates of return for the portfolios bought in the time between 11.03.2020-13.05.2020 – III period (43 trade days), the growth after the collapse of the market

Portfolios	Mean	Min	VaR 0.1	VaR 0.05	Semi-dev.	Std. Dev.	Skewness

In the third sub-period, the quotations of the WIG index slowly began to rise. During this period, purchasing an equally weighted portfolio proved to be a fairly effective method of risk diversification. The highest average rates of return, as in the second sub-period, were achieved by fundamental portfolios minimizing semi-variance. It is worth noting that the portfolios minimizing semi-variance had higher values of this risk measure compared to the portfolios minimizing the variance. At the same time, portfolios minimizing the variance had higher realized variances. However, taking into account the extreme values such as minimal return, VaR 0.05, VaR 0.01, there is a clear advantage of portfolios with minimized semi-variance. In the third sub-period, all portfolios are characterized by right-hand asymmetry and it is stronger than in the second sub-period.

Table 6: Summary statistics of the realized rates of return for the portfolios bought in the time between 14.05.2020-07.08.2020 – IV period (61 trade days), stabilization on the market

In the fourth sub-period there was a stabilization on the Warsaw Stock Exchange, the price increases were small, as it is shown at Figure 1. The realized rates of return for the equally weighted portfolios and those with minimum semi-variance were generally characterized by left asymmetry, and those with minimum variance - with right asymmetry. During this period, for many fundamental portfolios, the condition imposed on the given market ratio for the portfolio was not active, especially for market ratios based on various measures of the company's profitability.

In this period the most profitable were portfolios selected in accordance with the minimum variance criterion. The average rate of return for the equally weighted portfolios was quite high and the risk was lower than for Markowitz portfolios. In the fourth sub-period, advanced models of building the stock portfolio had similar usefulness for stock exchange investors as the simple method of selecting an equally portfolio.

In the entire research period (Table 7) portfolios with three criteria (mean return, risk and a fundamental criterion) allow for achieving higher realized returns compared to the equally weighted portfolio, portfolios minimizing risk (measure either with variance or semi-variance), or average return-risk portfolios. Additionally, it can be seen that the introduction of a fundamental criterion reduces the risk borne by an investor, measured both with standard deviation and semi-deviation. The analysis of extreme values (minimal return, VaR 0.1, VaR 0.05) also shows the advantage of fundamental portfolios. As one can see the whole group of portfolios minimizing semi-variance is characterized by a lower ex-post risk, compared to those minimizing variance. Fundamental portfolios have lower left asymmetry, especially for portfolios which was designed to minimalize semi-variance. It should be emphasized that lower left asymmetry is beneficial for investors, it means they are less exposed to very low rates of return.

Table 7: Summary statistics of the realized rates of return for the portfolio bought in the time between 21.11.2019-07.08.2020 – whole research period (177 trade days)

Portfolios	Mean	Min	VaR 0.1	VaR 0.05	Semi-dev.	Std. dev.	Skewness

Conclusions

In the paper fundamental portfolios both for variance and semi-variance approach was built. The iterative algorithm written in R- software was used for constructing portfolios in semi-variance framework.

For fundamental portfolios three criteria is considered: profitability (measured with expected return), risk (measured with variance or semi-variance of returns) and a market ratio of companies in the portfolio. Five different market ratios were used in the study. The usefulness of portfolio selection models during the Covid-19 epidemic was analyzed. This period has been divided into four sub-periods due to the changing situation on the Warsaw Stock Exchange.

During this period of the collapse on financial markets The worse strategy was to select an equally weighted portfolio. It was the least profitable and the most risky one, taking into account, Value-at-Risk and semi-deviation. It can be noticed that the most safe and at the same time the most profitable were the fundamental portfolios that minimize semi-variance.

In the entire research period portfolios with three criteria (mean return, risk and a fundamental criterion) allow for achieving higher realized returns compared to the equally weighted portfolio, portfolios minimizing risk (measure either with variance or semi-variance), or average return-risk portfolios. Additionally, it can be seen that the introduction of the fundamental criterion reduces the risk borne by an investor, measured both with standard deviation and semi-deviation. The analysis of Value-at-Risk also shows the advantage of fundamental portfolios. It can be noticed that the whole group of portfolios minimizing semi-variance is characterized by a lower ex-post risk, compared to those minimizing the variance.

The results from empirical research for the major companies traded on the Warsaw Stock Exchange reveals that:

- investors can received better investment results by adding to the Markowitz model, the additional criterion connected with market ratio such as book to market or earnings to market;
- using semi-variance instead of variance gives better results for investors, it is clear seen in the period of collapse on the capital market;
- fundamental portfolios with the minimum semi-variance seem to be the useful tool of choosing investment strategy during the Covid-19 pandemic.

The Use of Volunteering as An Indirect Source of Financing for Public Benefit Activity on The Example of Polish Foundations and Associations

Anna STASZEL

zieniukp@uek.krakow.pl

Abstract

Public benefit organisations are increasingly using volunteers, i.e. people who provide services voluntarily and without remuneration. Simultaneously, an increase in interest can be observed in problems such as the need for legal regulation of volunteering, elimination of tax barriers or ensuring the reimbursement of necessary costs incurred by volunteers in connection with the provision of services for the organisation. In Poland, there are detailed legal regulations on volunteering, compliant with EU requirements, which were presented in this study. It also presents the results of the authors' own research, carried out on a sample of 100 randomly selected public benefit organisations operating in the form of foundations and associations, conducting their activities in Poland. The aim of the research was to present the interrelationships between the number of volunteers involved in the organisation's activities and factors specific to the organisation, such as: territorial range, number of beneficiaries, duration of public benefit activities, number of employees employed and the amount of operating costs incurred and income generated. The research was performed on the basis of data from financial and substantive statements of the selected organisations. The following statistical methods were used to verify the formulated hypotheses: t test for independent samples and ANOVA variance analysis. The results of the research allow for a statistically significant correlation between the number of volunteers and the territorial range of activities carried out by the organisations and the amount of income generated. Thus, it can be said that voluntary activity is more prevalent in organisations with lower incomes which, without the help of volunteers, would not be able to carry out the current range of public benefit activities, due to a lack of resources to recruit staff and finance salaries.

Keywords: volunteering, public benefit organizations, foundations, associations, sources of financing for public benefit activities

Introduction

Voluntary and unpaid charity work is one of the factors enabling the development of public benefit organisations. It is characteristic of these entities to be able to benefit from volunteer services which correspond to work but are not paid. Therefore, there can be two groups of service providers - employees and volunteers - in non-profit organisations. For organisations, this means a reduction in the costs associated with payment of salaries.

Dynamic development of volunteering is an evidence of the realisation of the idea of civil society. However, it is very difficult to measure actual voluntary activity, due to the fact of frequent use of the results of surveys in which volunteers themselves determine the extent of their involvement in the organisation's activities, without giving a specific number of hours of work for the benefit of the organisation. In view of the above, the empirical research used a method of analysing the content of financial and substantive statements, in which data on volunteer activity in individual organisations accepted for the research sample were provided by organisations using volunteers.

The aim of the research, carried out on a sample of 100 randomly selected public benefit organisations, was to show the interrelationships between the number of volunteers and factors specific to the organisation. The following hypotheses have been verified:

Cite this Article as: Anna STASZEL and Pawel ZIENIUK "The Use of Volunteering as An Indirect Source of Financing for Public Benefit Activity on The Example of Polish Foundations and Associations" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- H1: "Public benefit organisations in which there are no volunteers are organisations with a significantly shorter period of operation than organisations involving volunteers"
- H2: "Public benefit organisations with more volunteers help more beneficiaries".
- H3: "Public benefit organisations with a larger number of volunteers carry out activities with a larger territorial range".
- H4: "Organisations where there are no volunteers incur significantly higher operating costs than those where there are volunteers".
- H5: "Organisations where there are no volunteers employ significantly more staff than organisations where there are volunteers".
- H6: "Organisations where there are no volunteers have a significantly higher income than organisations where there are volunteers".

The t-test for independent samples and the ANOVA variance analysis were used to confirm or deny the statistical significance of the relationship between the variables. According to the intention of the authors, the verification of the formulated hypotheses was to allow the basic conclusions to be drawn, leading to an assessment of the use of volunteering as an indirect source of financing for public benefit organisations.

Theoretical Background and Literature Review

Volunteering as an indirect source of funding for public benefit activities in European Union countries

In European countries, there is a wide variety of sources of funding for the activities of public benefit organisations. The results of the conducted research (Davister, Defourny, Gregoire, 2008) distinguish three basic groups of financing: domination of market sources (e.g. Belgium, Spain, Finland), public subsidies (e.g. Germany, Great Britain) and donations and volunteering (Great Britain, Spain). In the case of Poland, public sources of funding for public benefit activities are still dominant (Mamcarczyk, Zieniuk, 2020). However, the financing of these activities by organisations from their business activities and the "1% personal income tax mechanism", which has been in place since 2003, according to which Polish taxpayers may decide to transfer part of their income tax to a selected organisation for statutory purposes, are becoming increasingly important. Similar legal solutions have so far been introduced in other European countries, too, such as: Hungary (1%), Slovakia (0.5-2%), Lithuania (2%), Romania (3.5%), Slovenia (2%) and Moldova (2%).

The structure of the sources of financing of public benefit organisations is influenced by the country in which they operate. In the Rhine model, which exists, among others, in Belgium and France, NGOs are the main provider of public services contracted by the state. In the Scandinavian model (Sweden, Norway), organisations report the existence of social problems, but the state is the implementer of social policy. The Mediterranean model (e.g. Portugal) is characterised by a low level of independence and autonomy of organisations. In the Anglo-Saxon model (Great Britain) there is a high degree of professionalism and marketisation of the organisation. In the case of countries such as Poland or the Czech Republic, there is a model of a transition period characterised by dynamic development of organisations resulting from formation of civil society.

All European legal systems in which charitable organisations operate are characterised by the possibility for organisations to benefit from unpaid voluntary services. Unlike the typical sources of direct public and private funding of organisations, such as grants and donations, volunteering is considered a form of indirect funding. In this case, the organisation does not receive the funds it can use to carry out its statutory tasks. Funding of activities by volunteering should be seen in the context of the resources saved, as volunteers do not have to be paid for their services to the organisation. Therefore, the use of volunteer services gives organisations the opportunity to reduce costs of their activities. To illustrate the scale of these savings, it would be necessary to calculate the value of remuneration that would have to be granted to employees carrying out the same activities that volunteers do free of charge.

Volunteers carry out targeted assistance activities that extend over time and have been freely chosen by them. They do not expect an award for them and they carry out these activities through formal organisations, for people who need support (Kartika Dewi, Manochin, Belal, 2018). The reasons for undertaking voluntary activity include the desire to gain professional experience, increase personal competences, pass the internship, fulfil one's own needs in terms of values, search for space for self-fulfilment or gain professional contacts (Frączak, 2009). Young volunteers may be motivated by a desire for adventure, to make new contacts and friendships, to integrate into society, or to carry out social work as a punishment. For older people, however, involvement in voluntary work can help to maintain physical, intellectual and social fitness (Sznajder, Konopocka, Siorek, 2010). Young people have more

time and energy to use effectively for social activities (European Volunteer Centre, 2012). It has also been confirmed that it is more attractive for volunteers to provide services to specialist organisations that provide limited services with which they identify themselves to a greater extent (Lorente-Aayala, Vila-Lopez, Kuster-Boluda, 2020).

In countries characterised by a higher level of social capital, civic activity or trust, there is usually more developed volunteering (Pazderski, Sobesiak-Penszko, 2012). A Eurobarometer survey (2011) shows that in the Scandinavian countries, where around 56% of people are involved in volunteering, older people predominate. In southern European countries such as Greece and Portugal, only 4% of volunteers are elderly. In Poland, the percentage of people under 25 years of age devoting time to volunteering is twice as high as among people over 55 years of age. A similar situation persists in countries such as Lithuania, Latvia, Bulgaria and Romania.

Research on Polish NGOs is conducted by Klon/Jawor Association (2012). Their results indicate that about 44% of Polish NGOs use the work of volunteers, but only half of them cooperate with over 10 volunteers. Since 2002, more than half of Polish citizens have declared that they have been socially active. Similar involvement in social activity has been observed among men and women. The majority of volunteers are those with higher or secondary education.

Legal status of volunteering in Poland

The issue of volunteering was not explicitly regulated by EU regulations, only recommendations concerning social protection of volunteers and the movement of volunteers were introduced (Kołodziej, 2011). These recommendations include the obligation for the Member States of the European Union to prepare biennial reports on actions taken and problems relating to volunteering and to forward them to the European Commission. The recommendation covering volunteers with the right of free movement within the Community recommends that the members of the Union should take action to remove legal and administrative obstacles to voluntary activity. Other regulations on volunteering are shaped solely by domestic law.

The Polish legal system is governed by the Act on Public Benefit Activity and Volunteering (2003), according to which a volunteer is a person who provides services voluntarily and without remuneration under the terms of the Act. The legal relationship between an organisation and a volunteer is not an employment relationship, but a civil law relationship. The Act on Public Benefit Activity and Volunteering, which is in force in Poland, introduces the possibility of providing services by volunteers, corresponding to the provision of work, in the statutory activity of non-governmental organisations. The exact scope and modalities of the volunteer services and other detailed arrangements are determined in agreement with the beneficiary.

The introduction of the possibility of concluding agreements with volunteers in the Act on Public Benefit Activity and Volunteering has initially raised some doubts about the application of labour law to these people. However, neither the Act nor the Labour Code allows these provisions to apply to volunteering. On the other hand, defining volunteer services as "corresponding to the provision of work" is intended only to determine the essence of the activities covered by volunteer services, i.e. the performance of a specific type of work for the beneficiary, under the beneficiary's direction and at a fixed place and time (Gola, 2005). A volunteer who has made an agreement with an organisation may have the status of an unemployed person. Voluntary activity does not result in the loss of unemployment status or entitlement to allowance. There is also no obstacle to the volunteer becoming a working person, a retired person or a pensioner. Minors under 18 years of age must present the written consent of their legal representative when signing the agreement. Foreigners legally residing on the territory of the Republic of Poland can also become volunteers.

It should also be noted that in order to determine the rights and obligations of the parties, apart from the provisions of the Act on Public Benefit Activity and Volunteering, the provisions on the mandate contract and not on mutual agreements are applicable, as the volunteer does not receive for his or her services an equivalent of adequate financial value (Gola, 2005).

Volunteers have the opportunity to be reimbursed for expenses incurred in providing services to the organisation. In particular, the volunteer can be reimbursed for medical examinations, personal protective equipment, protective clothing, meals, business trips, telephone calls and training. This directory is open and reimbursement is conditional on a direct link to the volunteer's services to the organisation. In turn, the Act allows public benefit organisations to include the above costs in the costs of conducting public benefit activities.

A public benefit organisation may carry out unremunerated, unpaid activities as well as remunerated activities. In both cases, the organisation can benefit from the support of volunteers. The organisation may also register a

business activity, provided that profits from that activity are transferred to carry out its statutory tasks. It should be pointed out at this point that it is not permissible to use volunteer services in connection with the business activity. Therefore, an organisation conducting business activity may use volunteers' assistance only in carrying out its statutory tasks (public benefit activity), and the costs related to volunteers' services may not be included in the costs of conducting business activity.

Volunteers are not paid for their work, but there are no regulations prohibiting organisations from awarding them bonuses and cash prizes. It is not a pay for specific work done in a given period, but only an additional benefit component (Kasprzak, 2008).

Empirical Research

The research covered organisations with the status of public benefit organisations, operating in Poland and publishing financial and substantive statements in the Database of Financial and Substantive Statements of Public Benefit Organisations, run by the National Freedom Institute. The research sample included 100 organisations operating as foundations or associations, selected randomly, subject to constant selection interval. Selection of organisations to the sample meets the conditions of random selection.

The research was performed on the basis of data from financial and substantive statements published for 2019. The research used the content analysis method. Each of the sampled organisations has published the detailed information contained in the section of the "Volunteering during the reporting period" substantive statement. It is worth pointing out that all the organisations included into the survey sample fulfil their reporting obligations in a timely manner, making their financial and substantive statements public by publishing them in a database.

The data from the published financial and substantive statements were aggregated using a spreadsheet and then became the basis for statistical analyses. The following statistical methods have been used:

- t test for independent samples, the purpose of which is to compare averages from two independent groups,
- ANOVA variance analysis, the purpose of which is to explain with what probability the isolated factors may cause differences between the observed group averages.

The number of volunteers providing services to organisations included in the sample was recalculated. It is assumed that the number of volunteers who have worked with the organisation for less than 30 days, as shown in the content report, is primarily an action commitment. In determining the recalculated number of volunteers, a formula used in empirical research was used to determine the indicators of saved personnel costs (comp. Dyczkowski, 2015):

Recalculated number of volunteers = volunteers up to 30 days / 52 + volunteers over 30 days / 4

In order to verify the relationship between the number of volunteers working in public benefit organisations and the duration of the organisations' activities, the H1 hypothesis was verified, according to which: "Public benefit organisations in which there are no volunteers are organisations with a significantly shorter period of operation than those involving volunteers". Out of 100 analysed entities, 3 organisations operated the shortest (2 years), and 19 organisations operated the longest (over 15 years).

The average period of operation of organisations not involving volunteers is 11.2 years, while the average period of operation of PBOs in which voluntary activity occurs is 10.5 years. It can therefore be concluded that there are no significant differences between the period of operation of organisations that use volunteer assistance and those that do not. In order to verify the H1 hypothesis, a t-test for independent samples was used, the result of which is shown in Table 1.

Table 1: Result of the t-test to verify whether the average operation time of an organisation depends on whether the organisation uses volunteers.

Independent t tests for averages

F-ratio variance	1,135054
p-value variance	0,658368

Source: own elaboration based on data obtained from the conducted research

The results of the test show that the use of volunteer assistance by organisations is not differentiated by the duration of an entity's operation. Therefore, the H1 hypothesis stating that: "Public benefit organisations in which there are no volunteers are organisations with a significantly shorter lifespan than those involving volunteers", has not been confirmed.
In order to verify the relationship between the number of volunteers working in public benefit organisations and the number of beneficiaries of the organisation, the H2 hypothesis was verified: "Public benefit organisations with more volunteers help more beneficiaries".

The ANOVA test was used to verify whether there are significant differences in the number of beneficiaries in the separate groups of organisations A,B,C,D. In order to verify the hypothesis, a one-factor analysis of ANOVA variance was used to check whether the number of volunteers working in PBO significantly differentiates the number of people that the PBO helps.

Table 2 shows the average number of beneficiaries of organisations, depending on the number of volunteers in the organisation. Organisations of the survey sample were divided into four groups. On the other hand, Table 3 presents the results of the single-factor ANOVA variance analysis .

Table 2: Average number of beneficiaries of PBO assistance depending on the number of volunteers working in the PBO

Group	Average number of beneficiaries
Group A (Organisations in which there are no volunteers)	5429,455
Group B (less than 1 volunteer per year on average)	2075,000
Group C (more than 1 but less than 10 volunteers per year on average)	3217,593
Group D (more than 10 volunteers per year on average)	5254,750

Source: own elaboration based on data obtained from the conducted research

The data presented in Table 2 shows that the largest number of people are assisted by organisations with no volunteers, as well as those with more than 10 volunteers. Interestingly, the lowest average number of beneficiaries is in organisations with between 1 and 10 volunteers.

Table 3: The results of the single-factor ANOVA variance analysis

Variable: Number of beneficiaries of PBO assistance

MS error	234145085
F	0,284252
p	0,836660

Source: own elaboration based on data obtained from the conducted research

From the relationship shown in Table 3, it can be seen that the number of volunteers is not a factor that significantly differentiates the number of people that the foundation helps. Therefore, the H2 hypothesis stating that: "Public benefit organisations with more volunteers help more beneficiaries" has not been confirmed.

In order to verify the relationship between the number of volunteers working in public benefit organisations and the organisation's operational range, the H3 hypothesis was verified: "Public benefit organisations with a larger number of volunteers carry out activities with a larger territorial range".

In order to verify the hypothesis, a one-factor ANOVA variance analysis was used, which makes it possible to check whether the number of volunteers working in the PBO significantly differentiates the territorial range of the organisation. Table 4 compares the average numbers of volunteers in organisations carrying out activities of different territorial range. For each of the organisations included into the survey sample, its scope was marked, classifying the organisations into groups.

Table 4: Average number of volunteers according to the territorial range of the organisation.

Group	Average number of volunteers
Group 1 – closest vicinity	0,23352
Group 2 – municipality	0,49126
Group 3 – poviat	5,75801
Group 4 – voivodship	14,12500
Group 5 – whole country	2,54615

Source: own elaboration based on data obtained from the conducted research

The data presented in Table 4 shows that most volunteers operate in organisations with a voivodship range, followed by organisations with poviat range. Whether the observed differences between the average numbers of volunteers are statistically significant can be determined by means of the ANOVA variance analysis, the results of which are shown in Table 5.

Table 5: Results of one-factor of ANOVA variance analysis for the number of volunteers according to the territorial range of the organisation.

Variable: Average number of volunteers

p	0,039876

Source: own elaboration based on data obtained from the conducted research

The results of the test, presented in Table 5, show that the territorial scope of the organisation's activities is a factor that significantly differentiates the number of volunteers, thus confirming the H3 hypothesis: "Public benefit organisations with a larger number of volunteers carry out activities with a larger territorial range".

In order to verify the relationship between the use of volunteers and the recorded costs of the organisation's activities, the H4 hypothesis was verified, according to which: "Organisations where there are no volunteers incur significantly higher operating costs than those where there are volunteers".

The average cost of conducting activity in organisations of the survey sample with no volunteers amounted to PLN 885642.7, while the average cost in organisations using voluntary activity was PLN 836432.4. In the second group of organisations these costs are lower. To verify whether the differences observed are statistically significant, a t-test for independent samples was used, the result of which is shown in Table 6.

Table 6: Result of the t-test to verify whether the average costs borne by PBO depend on whether PBO uses volunteers.

Independent t tests for averages	
Group 1: Organizations that do not use volunteers vs Group 2: Organizations using the help of volunteers

Std. dev : Group 2	1568254
F-ratio variance	1,381527
p-value variance	0,255379

Source: own elaboration based on data obtained from the conducted research

The test results presented in Table 6 show that whether or not an organisation uses volunteers is not a factor that significantly differentiates the operating costs of the organisation. Therefore, the H4 hypothesis, stating that: "Organisations where there are no volunteers incur significantly higher operating costs than those where there are volunteers" has not been confirmed.

The relationship between the use of volunteers by organisations and the number of staff employed in the organisations was also verified. The verification covered the hypothesis H5, stating that: "Organisations where there are no volunteers employ significantly more staff than organisations where there are volunteers".

The average number of people employed in organisations with no volunteers is 23, while the average number of people employed in organisations with volunteers is 18. The employment has been converted into full-time equivalents, including both the persons employed in the organisations and those cooperating under a mandate contract and a contract for specific work. To verify whether the differences observed are significant, a t-test for independent samples was used, the result of which is shown in Table 7.

Table 7: The result of the t-test to verify whether the average number of employees in an organisation depends on whether the organisation uses volunteers

Independent t tests for averages	
Group 1: Organizations that do not use volunteers vs Group 2: Organizations using the help of volunteers	
Mean: Group 1	23,35962

Std. dev: Group 1	44,94647
Std. dev : Group 2	39,92038
F-ratio variance	1,267658
p-value variance	0,409425

Source: own elaboration based on data obtained from the conducted research

The results of the test, presented in Table 7, show that whether an organisation uses volunteers or not, is not a factor that significantly differentiates the number of people employed in the organisations. Therefore, the H5 hypothesis, stating that: "Organisations where there are no volunteers employ significantly more staff than organisations where there are volunteers" has not been confirmed.

It was also verified whether organisations that use volunteers have lower incomes than those that do not use volunteering. A positive verification would allow for the conclusion that organisations whose economic situation is worse, i.e. those with lower incomes, use volunteers' help.

The verification covered the H6 hypothesis, stating that: "Organisations where there are no volunteers have a significantly higher income than organisations where there are volunteers".

The average income in organisations with no volunteers amounts to PLN 501 thousand, while the average income in organisations with volunteers amounts to PLN 125 thousand, about four times less. To verify whether the differences observed are statistically significant, a t-test for independent samples was used, the result of which is shown in Table 8.

Table 8: Result of the t-test to verify whether the average income achieved by an organisation depends on whether the organisation uses volunteer assistance

Independent t tests for averages	
Group 1: Organizations that do not use volunteers vs Group 2: Organizations using the help of volunteers	
Mean: Group 1	1248031
Mean: Group 2	501315,5
t	2,064543
df	95
p	0,041692

Valid N: Group 2	48
Std. dev: Group 1	2453638
Std. dev : Group 2	512820,0
F-ratio variance	22,89238
p-value variance	0,000000

Source: own elaboration based on data obtained from the conducted research

The test results presented in Table 8 show that whether an organisation uses volunteers or not is a factor that significantly differentiates its income. Therefore, the H6 hypothesis, stating that: "Organisations where there are no volunteers have a significantly higher income than organisations where there are volunteers" has been confirmed.

Conclusion

Volunteering is a form of cooperation that benefits both parties to the agreement. The organisation obtains help with its activities, the volunteer gains experience which can be used in later professional work. Due to growing importance of the phenomenon of volunteering, there is an increasing number of operations in the activities of an organisation, concerning the services provided by volunteers, which need to be appropriately included in the accounting system. The specific nature of public benefit organisations should impose the need for reliable and transparent bookkeeping, which is particularly related to the fact that these organisations use public funds and carry out commissioned tasks. Proper implementation of the organisations' reporting obligations also allows for providing a wide range of recipients with detailed information on the statutory objectives pursued by the organisations and the resources used, including information on the number of employees and the scale of use of volunteering.

The specific nature of the activities carried out by public benefit purpose organisations, and in particular the purposes for which they are established, justify the possibility of using assistance from persons who provide services voluntarily and without remuneration. The legal regulations in force in Poland, concerning public benefit activities and volunteer services, should be considered to be in line with EU guidelines. Simultaneously, tax preferences, linked to the lack of taxation of voluntary activity, are the legislator's incentive to establish organisations and carry out voluntary work.

The theoretical considerations carried out in this study and the results of the empirical research presented here confirm that the possibility for public benefit organisations to use voluntary activities is a source of indirect funding for their activities. In particular, the statistically significant relationship between the number of volunteers working for the organisation and the amount of income generated by the organisation should be highlighted. The scale of using volunteers is greater in organisations with lower annual revenues. If, therefore, it were not possible for these organisations to use volunteer services unpaid, they would have to reduce the scope of their public benefit tasks, as

it is not possible to finance the salaries of employees carrying out tasks to the same extent as current volunteers. There was also a statistically significant correlation between the number of volunteers and the territorial coverage of the organisation. This relationship seems understandable, since organisations operating in a larger area of the country are usually entities which carry out more statutory tasks. However, in the adopted sample, no statistically significant relationships were found between the number of volunteers and the number of beneficiaries of the organisations, the duration of the organisations' activities, the number of employees employed and the level of costs incurred by the organisations.

Abstract

The article is devoted to the study of the ways of development of foreign economic activity of large Russian industrial regions. The authors substantiated the key guidelines for the diversification of national exports and showed that its successful development is based on the interaction of the federal center and regions. On the example of a large industrial region - the Chelyabinsk region, promising geographical directions for the development of regional exports are identified and ways of developing each of the directions are proposed. The authors have proposed branches of the regional economy that are promising in terms of export development - metallurgical, agro-industrial, transport and nuclear complexes, mechanical engineering, tourism, education and science. Based on the study, the article identifies the key directions of export development - strengthening the image of the region, international product promotion and attracting foreign capital.

Keywords: Regional Economy, Foreign Economic Activity, Export Activities, Export Support.

Introduction

The development of foreign economic activity has a positive impact on the rates of economic growth of the subjects of the Russian Federation. This topic is especially relevant for large industrial regions of Russia of the raw material type, experiencing crisis and post-crisis trends. This determines the relevance of the research topic and the choice of the foreign economic activity of the Chelyabinsk region as its subject.

Currently, the key documents setting specific tasks in the field of foreign economic activity are the Russian state program "Development of foreign economic activity" and the Action Plan "Support for access to foreign markets and export support". The goals of the Program are to strengthen positions in the global economy and increase the contribution of foreign economic activity to the country's socio-economic development. The objectives of the Program are to strengthen international cooperation, develop a system of state regulation, institutions and mechanisms of foreign economic activity and customs administration, increase the efficiency of checkpoints across the state border.

The listed goals and objectives are guidelines for the development of foreign economic activity of Russian regions and key guidelines for export diversification:

ANASTASOV "Determination of Perspective Directions for The Foreign Economic Activity Development in Large Russian Industrial Regions (On the Example of The Chelyabinsk Region)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- natural production diversification - consolidation of existing advantages, as well as expanding the processing of primary resources and moving up the value chain;

- innovative diversification - modernization of the export assortment on the basis of strengthening the system of competitive advantages, the formation of competitive industries, concentrating on the final stages of the technological cycle and ensuring high dynamics of innovation.

At the same time, the national export development system can function effectively only if the efforts of the federal center and the subjects of the Russian Federation are consolidated. At the same time, most of the Russian regions are poorly oriented towards foreign markets and their products are not competitive enough. Let us consider the situation using the example of one of the typical regions of Russia in this regard - the Chelyabinsk region.

Results and Discussion

From an institutional point of view, a number of export support institutions operate in the region. The concept of a "single window" has been implemented as the main element of interaction between government and business. There is an Export Support Center that provides consulting and analytical assistance to increase the number of exporters and revenue from export deliveries. The Industry Support Fund is functioning, support for innovative enterprises is provided by the Center for Cluster Development.

Geographically, promising directions for the development of the region's foreign economic activity can, according to the authors, be divided into the following areas:

1. Interaction with the SCO, including:
- SCO members - China, Kazakhstan, Kyrgyzstan, Tajikistan, Uzbekistan, India, Pakistan;
- SCO observers - Belarus, Afghanistan, Iran, Mongolia;
- candidates for SCO membership - Syria, Bangladesh, Egypt.

To organize cooperation in this market segment, it is advisable, from our point of view, to establish long-term interaction between economic entities, expand the use of transit corridors and logistics complexes in the region, support investment projects of regional business abroad; interaction in the field of tourism and attraction of direct foreign investments to the region.

2. Cooperation with China in the scientific and technical sphere and the creation of joint production zones.
3. Interaction with the BRICS countries - Brazil, India, China, South Africa in the following areas:
- development of long-term cooperation between business entities;
- participation of regional enterprises in infrastructure projects of the BRICS countries;
- expansion of transport and infrastructure cooperation, etc.
4. Deepening interaction with the EAEU countries - Armenia, Belarus, Kazakhstan and Kyrgyzstan.
5. Interaction with the EU countries in the following areas:
- establishment of cooperation between business entities;
- use of transport and logistics corridors for the movement of transit cargo in the region;
- interaction in the field of tourism;
- attracting investments and technologies to the region;
- support of investment projects of regional business abroad;
6. Cooperation with other regions - Iran, Kuwait, Turkey, Egypt, Vietnam, Japan, South Korea, etc. in the following areas:
- building up trade and economic cooperation and expanding bilateral trade in the agro-industrial sector, supporting investment projects of regional business abroad (South Korea);
- introduction of environmentally friendly technologies, waste processing, development of consulting, organization of joint ventures in instrument making, machine and machine tool building (Japan);

- attracting investments and technologies to the region (Canada, South Africa);

- expanding bilateral trade, attracting investment and expanding technological cooperation (North America);

- cooperation in science, technology and trade, support for regional investment projects in mechanical engineering, metallurgy, IT-sphere, pharmacy (India);

- participation of regional enterprises in foreign infrastructure projects, promotion of products of regional enterprises in the field of mechanical engineering, metallurgy, industrial equipment, construction industry, energy, military-industrial complex, as well as development of investment cooperation (Middle East).

According to the authors, it is expedient to include the following as promising sectoral directions for the development of the region's foreign economic activity:

1. Metallurgical complex.
2. Agro-industrial complex.
3. Mechanical engineering.
4. Transport complex, primarily international transit services across the region.
5. Tourism sector.
6. Education and science.
7. Atomic complex.
8. The field of information technology and telecommunications, including software development services and mobile radio services.

Let's consider these directions in more detail.

The metallurgical complex of the region provides more than 12% of Russia's non-resource exports and is capable of providing 11% of its growth. The largest part of exports is related to steel in the form of semi-finished products and rolled products. A significant part is accounted for by aluminum, copper, nickel, ferrous metal products and steel pipes. Titanium, ferroalloys, products of direct reduction of iron ore, small and rare metals are promising in terms of increasing exports. The export structure consists of:

- ferrous metals (and products from them) - more than 80% of the export of metals;
- non-ferrous metals (and products made from them) - about 20% of metal exports;
- copper (and products made from it) - about 87% of the export of non-ferrous metals;
- nickel (and products from it) - about 8% of the export of non-ferrous metals.

The foregoing allows us to assert that the metallurgical complex is one of the priority directions of the region's foreign economic activity.

The agro-industrial complex of the region provides about 8% of Russia's non-primary exports, and the greatest potential for its increase is associated, according to the authors, with fertilizers and grain. It is significant for fish and seafood, vegetable oils and feed. In addition, meat, confectionery, alcoholic beverages, tobacco products, fruits and vegetables, sugar, flour, agricultural machinery and agrochemicals have a significant export potential to the markets of neighboring countries. The agro-industrial complex of the region provides for the export of vegetable processing products, fat-and-oil and flour-and-cereal products, flour and confectionery products, cereals, meat and meat offal, as well as dairy products. At present, supplies of food products and raw materials for their production account for just over 2.5% of regional exports. It can be argued that the level of development of the agro-industrial complex, the quality and competitiveness of products, as well as production volumes allow us to consider this direction as promising for the development of the region's exports.

Mechanical engineering is one of the priority industries for the region. Machine-building enterprises produce over 12% of the region's industrial products, including:

- machinery and equipment - mechanical, rolling, blast furnace and steel-making equipment, cranes, loaders, machine tools, tractors, bulldozers, road machinery, agricultural machinery and equipment;
- vehicles and equipment - cars, car trailers and semi-trailers, locomotives, tram cars, etc.

The transport complex of the region has a great export potential. Possessing a geographically advantageous location, the Chelyabinsk Region demonstrates significant opportunities in the provision of transit services, which, according to the authors, will increase with the development of transit transport infrastructure and the organization of transport corridors: high-speed railways and highways.

Tourism is one of the points of growth of the foreign economic activity of the regional economy, which may become system-forming in the future. This is due to the following reasons:

- rich recreational resources of the western part of the region: a large number of lakes and national parks;
- numerous historical monuments presented by the Arkaim Museum-Reserve, unique monuments of ancient metallurgical production, etc.;
- developed tourist infrastructure, which is actively developing and reconstructing in recent years.

Educational and research services currently provide small volumes of export, but are important for attracting personnel to the region and creating an environment for the development of business cooperation with foreign countries. According to the authors, the export of education should be understood as attracting foreign students, increasing foreign students of online courses and foreign schoolchildren receiving additional education in the region. The Chelyabinsk Region belongs to the developed industrial regions of the country and has rich scientific and educational resources.

The significant export potential of the region is associated with the nuclear complex and, first of all, with services for decommissioning nuclear power plants, processing spent nuclear fuel, and supplies of nuclear fuel and isotopes. The largest increase in exports can be expected, according to the authors, to Southeast Asia, Eastern Europe, the Middle East and North Africa.

The region is home to the centers of the nuclear industry. The accumulated experience and unique competencies allow us to consider international cooperation in the atomic sphere as one of the promising directions for the development of foreign economic activity. The competitiveness of the nuclear complex is due to the developed scientific, technical and production base, the expansion of state investments in this area and the modernization of the fixed assets of science-intensive industries.

Another point of growth of the region's foreign economic activity is the IT and telecommunications sector, including software development and mobile radio communication services. At the same time, the development of this area requires government support due to the high capital intensity and long-term payback of projects. The key tools in this area are the development of a network of technoparks, innovation and technology centers, the formation of a system of state support for start-up innovative IT companies and the development of institutions for the protection of intellectual property.

Thus, it is advisable to group the promising directions of development of the region's foreign economic activity in the following areas:

- development of international relations and strengthening of the region's image in the world market;
- international promotion of products of regional enterprises;
- increasing the investment attractiveness of the region, raising capital and setting up joint ventures.

Abstract

The article is devoted to the study of human resource management in the field of education based on the competence approach. The purpose of the research is to identify modern problems of teaching staff management, as well as to identify the composition of the teacher's competencies that determine the success of his professional activity. The authors present the structure of the human resource management system in the field of education. The specificity of the competence approach in education as an instrument for solving life problems based on the development of various competencies is revealed. The article gives the analysis of approaches to the definition of "competence" and "competency" from the perspective of domestic and foreign researchers. On this basis, the author's definition for the concept «competence"is formulated. The main problems that arise in the process of managing human resources in education are identified, as well as the main requirements to compose the professional competence of a modern teacher. The model of teacher's professional competence has been developed. It is proposed to use individually differentiated educational routes as a way to improve the professional competence of a teacher.

Keywords: Human Resource, Education, Competence Approach, Management.

Introduction

The progressive development of modern society is accompanied by the formation of new economic relations based on horizontal and vertical links between economic entities. Under such conditions, a large role is assigned to the qualitative characteristics of knowledge, skills, abilities, and other parameters that are combined in the category of "human resources".

In the post-industrial economy, the leading force is the knowledge base, which is formed in the field of education based on the competence approach. Thus, an important characteristic of human resources is professional competence as a set of competencies developed by each specialist.

Literature Review

Research in the field of human resource management based on the competence approach in the field of education is of considerable interest to both domestic and foreign scientists. The expediency of using the competence approach and the close relationship between the concepts of "competence" and" competency" are evidenced by the works of V.L. Akapyev, M.A. Akopyan, A.P. Akimova, V.N. Vvedensky, V.R. Vesnin, V.I. Volynkin, B.S. Gershunsky, V.Yu. Krichevsky, A.K. Markova, D.J. Raven, D.S. Savelyev, M.A. Choshanov, O.V. Yadryshnikova, and others. Analyzing the works of Russian scientists, we can note a steady tendency for the analyzed concepts to be understood differently in content, although some scientists, such as N.D. Nikandrov, V.S. Lednev, M.V. Ryzhakov, N.D. Galskova, Z.I. Klychnikova, E.N. Solovova, and others, identify these concepts. The works of G.E. Belitskaya, L.I. Berestova, E.V. Bondarevskaya, A.S. Guseva, O.I. Denisov, A.A. Derkach, I.N. Drozdov, S.A. Druzhilov, I.V. Elshina, N.N. Yershov, T.V. Krotova, N.N. Lobanova, V.N. Makarova, V.N. Markin, V.G. Pervutinsky, A.P. Sitnikov, V.D. Shadrikov, E.N. Yurina and others are devoted to the essence of the competence approach in education.

In the context of the categorical apparatus for the competence approach, it is necessary to dwell in more detail on the definition of the concept "competence" by a number of Russian scientists. Revealing the essence of professional competence, V.N. Vvedensky (2004) notes that this category cannot be reduced to a set of knowledge, skills and abilities. Its conceptual characteristic is "effective application of the individual capabilitiescomplex in solving professional problems". According to A.M. Aronov (2010), the criterion for the effectiveness of competence formation is the ability and readiness of an individual to be engaged in specific activities. Researchers V.S. Bezrukova, S.M. Vishnyakova, and V. Shepel emphasize the professional component of competence and focus on its operational activity and cognitive components (Kostrova, 2011). Nechaev's approach is based on the understanding of competence as an individual's possession of special professionally significant knowledge, understanding the specifics of labor activity in the relationship of its phenomena and processes, and possession of ways and means to achieve the intended goals (Nechaev and Reznitskaya, 2014). A.K. Markova notes the individuality of competence, which is expressed in the compliance degree of the individual with the requirements of the profession, in his ability to act independently and responsibly performing his work functions. Competence, as defined by M.P. Lapchik, is a formed stock of knowledge, skills and methods of activity set in relation to a specific range of subjects and processes that are necessary for high-quality productive activity. The personal component of competence is mentioned in the works of N.V. Kuzmina, where the author emphasizes the ability of an individual to form personal qualities in the process of mastering his specialty (Kuzmina and Rean, 1993).

Research Question

Drawing attention to the quality side of human resources allows a deeper study of professional competence, taking into account global trends. Among them are the following ones:

- changing demographic situation, when population growth in some countries is accompanied by a shortage of human resources in other countries;
- overflow of human resources between countries can lead to 2050, growth in developing economies of the E7 (China, India, Brazil, Russia, Indonesia, Mexico, Turkey) more than 6 times the level of global competition;
- accelerating urban growth, which will improve the quality of life and enrich human resources;
- climate change and resource scarcity, which is an increasingly significant threat to the economy;
- a breakthrough in the field of technology, which requires the development of new competencies by employees.

Assessing the impact of all these trends, we note that Russian and international companies have different assessments of their influence on human resource quality management. While they agree that demographic problems are dominant, they grade the other components differently (figure 1).

Figure 1- The impact of the driving economic forces on the quality of human resources from the perspective of Russian and international companies (PwC, 2014)

These trends affect changes in the requirements for both professional competence and understanding of its composition. Research by PricewaterhouseCoopers LLP has shown that it is necessary to use the available human resources more effectively for the progressive development of the economy. Creativity was recognized as the most significant quality of human resources that will contribute to the stabilization of the world economy. The presence of creative elements is the result of scientific and technological progress in society. This quality of human resources leads to the formation of a creative employee who is able to generate new ideas. For example, P. Florida considers human creativity to be the most important driving force of the new economy (Florida, 2007). Creativity is mainly expressed in the employee's ability to create images of future products, which makes it a necessary component of an innovative economy.

Under such conditions, the effectiveness of human resource development is determined by the existing management system. According to Professor B.V. Salikhov, it is a process of purposeful impact on the integrity and interrelated unity of the object, process, project and environment subsystems that determine the direction and content of human capital development (Salikhov, 2008). Figure 2 shows the proposed scheme to organize the human resource management system in the field of education.

The development of human resources takes place through the development of key competencies in the process of continuing education and professional development. According to UNESCO, the traditional content of the concept "qualification" is giving way to the concept "competence" in many areas of human life. In this context, J. Raven indicates evolutionary competence and adaptability (Raven, 2002).

Figure 2- Human resource management system in the field of education

The transition from the accumulation of knowledge and skills to the formation of professional competencies has occurred relatively recently. With the introduction of the third-generation FSES in the field of education, there has been an essential change in approaches to education. Training of specialists has become competently oriented. The competence approach accumulates general principles for all levels of the education system in determining:

- educational goals;
- content of educational programs and modules;
- ways to organize the educational process;
- evaluation of the educational processresults.

The purpose of the educational process from the position of this approach is to form and develop the ability of students to solve various problems based on their own experience. The content of education is an adapted social experience of solving life problems (cognitive, ideological, moral, political, etc.). In the process of organizing educational activities, conditions are created that contribute to the formation of students' ability to solve such life problemsindependently. Evaluation of the educational process results is to determine the education level of the student at each stage of training.

This approach is based on the understanding of competence and competency as an integral social, personal and behavioral phenomenon, as a result of the educational process. At the same time, the definition of this approach does not have unambiguous characteristics, although in the most general form, the positions of many researchers coincide.

The competence approach is humanitarian in its core, since it is directly related to the idea of comprehensive training and education of an individual not only as a specialist, professional in this or that sphere, but also as a person and a member of the team and society. After all, the goal of humanitarian education is to form humanistic values, personal worldview of a person, develop his horizons, ability to make individual creative decisions, and self-study, and not just to transfer and interpret the system of knowledge about the world, as in pragmatic training. All this reflects the specifics of the competence approach (Makarova (ed), 2013).

In general, the competence approach in education is reduced to getting students experience in solving life problems based on the development of various kinds of competencies. It is based on such basic concepts as "competence"and "competency". There is no consensus on the relationship between these concepts in the scientific world, although active work is underway to identify the essence and content for each of them. Currently, according to I. A. Zimnaya, there are two possible ways to interpret the relationship between these concepts: "they are either identified or differentiated" (Leskina, 2012). At the same time, the collective monograph edited by Professor V.N. Makarova identifies 10 approaches to solving the problem of the relationship between the concepts of "competence" and "competency" (Makarova (ed), 2013), which reflects the views of many Russian and foreign researchers. An analysis of the works of Russian scientists to understand the concepts of "competence" and "competency" is given in table 1.

Table 1-Approaches to defining the concepts of "competence" and "competency"

Author	Content of the concept	
	competency	competence
V.I. Dal	did not examine	full rights
S.I. Ozhegov N.Yu. Shvedova	range of issues which someone is well aware of	possession of knowledge, awareness, authority in some sphere
A.S. Melnichuk E.V. Selezneva	competence is considered as a set of competencies	
A.V. Khutorskoy	given social requirement (norm) to the educational preparation	possession of the relevant competency, including the personal attitude to it and the subject of activity
I.A. Zimnaya	internal, potential, hidden psychological neoplasms (knowledge, ideas, programs (algorithms))	actual, active manifestations
A.K. Markova	objective characteristics (scope of duties and rights of a responsible person)	subjective characteristics of social, personal, spiritual, professional qualities as an integrative characteristic of a person
V.I. Zagvyazinskiy	generalized methods of actions that ensure the productive performance of professional and other activities in a particular sphere	internal psychological neoplasms of the individual: systems of values and relationships, knowledge, experience, ideas, programs (algorithms) of activity, creative abilities that allow to implement competencies
A.G. Bermus	a set of interrelated personality traits given in relation to a certain range of objects and processes	possession of the relevant competency, including the personal attitude to it and the subject of activity
G.K. Selevko	the result expressed in the graduate readiness for the real possession of methods and means of activity	an integral quality of the individual that manifests itself in the general ability and readiness for activities based on knowledge and experience
A.I. Surygin	the content of the relevant competence in the form of a system of knowledge, skills, experience and the degree of satisfactory mastery of certain norms of communication, behavior as a result of learning	the ability of the individual to perform any activity or actions, the ability to establish and maintain the necessary contacts between people
T.Yu. Bazarov	requirements for successful performance, formulated in terms of the integral qualities of a collective or individual subject	the set of personal characteristics, including abilities, motives and goals that a specialist should have within a given range of competencies required for a particular job.

In the research of foreign scientists, the concept of "competency" is rarely used. We can talk about the predominant use of the concept "competence" to denote the ability or readiness of an individual to mobilize individual resources (as a set of knowledge, skills and mental qualities of the individual) necessary to perform tasks at a high level in accordance with a specific life situation. Thus, in the Glossary of terms of the European Education Foundation, the following definition of the concept of "competence" is given (Lakhova, 2020):

- it is an ability to do something well or effectively;
- it is a compliance with the requirements for employment;
- it is an ability to perform specific labor functions.

In European society, the concept of "key competences" is quite widespread, which are universal skills and abilities of an individual, thanks to which they are able to consciously make decisions and achieve final results in a certain area of their activity (Spravochnick, 2020). The European Commission's recommendations on key competences for lifelong learning, developed in 2018, contain eight key personal competences that meet the needs of European society for sustainable economic growth, social cohesion and the development of a democratic culture. Key competences are developed from early childhood throughout life through formal, non-formal and informal education. Key competences, according to the recommendations of the European Commission, are (European Commission, 2020):

- literacy competence;
- language competence;
- mathematical competence, as well as competence in the field of science, technology, engineering;
- digital competence;
- personal, social and learning competence;
- civil competence;
- entrepreneurship competence;
- cultural awareness and expression competence.

The main idea of the competence approach is that each individual should independently, based on their life experience and accumulated knowledge, organize them, develop their own ways of obtaining new knowledge, methods for solving emerging problems, and adapt to changing conditions of social life. Professional competence includes the following components:

- operational and technological (cognitive);
- social;
- motivational and value-based;
- emotional;
- activity.

The level of a personal competence finds real expression in his personal achievements in specific areas of life. Thus, competence can be defined as an integral characteristic of an individual's personality. The constituent elements of competence in different conditions will be a different set of competencies that an individual has. The main link of any competence is a specific action.

Modern research suggests that there are many types of competence. The application of each specific set of them on the whole will be determined by the nature of the individual's professional activity. However, despite this, it is necessary to distinguish a number of components that are "universal" and mandatory for each profession in the field of education (Figure 3).

PROFESSIONAL COMPETENCE

Emotional and volitional component	personal attitude of the specialist to the problem, his feelings, emotions, priorities, his ability to adequate self-esteem, self-regulation of behavior
Motivational and value componen	the readiness of a specialist to carry out professional activities independently that are not strictly set from the outside (subjective side) and the presence of alternatives for solving problem situations (objective side)
Cognitive component	cognitive abilities of specialists: the ability to perceive educational and informational material and the presence of a certain "baggage" of knowledge (intellectual involvement, interest in science, openness to the acquisition of new knowledge, professional knowledge, skills)
Communication component	features of a specialist interaction with the social environment under conditions of personal freedom (ability to build a dialogue; construction of potential social requests based on the existing database of situations)
Creative and activity component	applying a creative approach to work, thereby forming the ability to choose a set of methods and technologies of work consciously (designing prospects for development and results of professional activity; creative independence in solving professional problems; "correct" problem statement, the ability to anticipate the occurrence of a problem situation and build a system of preventive measures on this basis)

Figure 3 - Components of professional competence (Baryshnikova, 2012)

Among the trends in the development of modern education, we note the following:

- introduction of Federal state educational standards of a new generation;
- implementation of inclusive education;
- development of regional systems for assessing the quality of education, etc.
- complication of teachers' professional activities, accompanied by high intellectual and emotional stress, as well as overcoming professional difficulties.

At the same time, the implementation of educational activities is accompanied with an update of the organizational and methodological support of the teacher's activity, since all innovations in the field of education affect the performance of their professional tasks. It is the teacher, in the final analysis, who is the executor of all innovations in the field of education. According to the practice, to implement a given pace of updating the educational process, a teacher must have an appropriate set of professional competences, which is not always observed.

In this regard, the problem of improving the professional competence of a teacher has become particularly relevant. It is important not to contrast the need for regular improvement of professional competence with the processes of creative self-development, activation and stimulation of teacher's self-education in everyday activities. While improving their competences in the course of education and self-education, a teacher should still be guided by the standards and norms accepted in society, and strive to master relevant and innovative professional competences. After all, it is the combination of competence and qualification that ultimately determines the vector of personal and professional development of a teacher. In its turn, it is possible to form and develop professional competence only if the teacher has a certain level of accumulated knowledge, skills, personal and professional qualities and attitudes.

Current regulatory documents (for example, the Federal Law "on education in the Russian Federation", Federal state educational standards, professional standards) regulate professional competences a modern teacher needs to develop. However, they do not answer the question "How should a specific teacher improve his level of professional competence?". This contradiction is the main problem of human resource management in education. The regulatory documents clearly specify which competences need to be developed, but the way of its achievement is not defined in any of the regulatory documents. Under such circumstances, it is necessary to develop and formulate methods for improving the professional competence of teachers.

Each teacher has the right to choose his own way of development, his own individual educational route. But very often it becomes another problem of human resource management in education. Due to the large professional employment and document load, it is easier for a modern teacher to follow the do-path, when instructions are offered, according to which he can achieve a certain goal, which is expressed in increasing the level of professional competence.

Modern Federal state educational standards set requirements for the level of qualification of employees in an educational organization: for each position held, he/she must meet the requirements specified in the qualification reference books and/or professional standards. In addition, these standards establish the need for continuous professional development through the system of additional education in the profile of pedagogical activity at least once every three years.

The synthesis of modern developments in the research on the content of teachers' professional competence and the provisions of regulatory documents allowed us to determine the main requirements for the components of educational workers' professional competence:

- pedagogical competence in the field of design and implementation of the educational process in educational organizations;
- pedagogical competence in the design and implementation of basic educational programs and their components.

On the basis of general requirements to the content of a teacher's professional activity, four directions of professional activity are identified:
- general pedagogical (training) activities;
- educational activities;
- development activities;
- pedagogical activities for the implementation of programs at all levels of education.

In our view, pedagogical competence is a complex symbiosis of social experience, theoretical knowledge, practical skills, and personal qualities. All of them makes it possible to perform pedagogical functions in accordance with the standards and norms of the educational process organization accepted in the society.

It can be argued that the educational process and professional competence of the teacher are inextricably linked. They have a direct effect on each other. As a result, the structural components of pedagogical competence should coincide with the components of pedagogical activity. Therefore, the structural and content model of a teacher's professional competence acts as a unity of his theoretical and practical readiness for action in the course of the educational process.

Based on the analysis of regulatory documents and previously created models of professional competence, we have compiled a general structural and content model that serves as the basis for further design of professional development programs. It is shown schematically in figure 4.

Figure 4 - Model of a teacher's professional competence

Thus, the starting point of building a theoretical model of a teacher's professional competence was the analysis of professional activities that this teacher should be well prepared to perform. The solution of problems in the field of human resource management in the field of education is possible through the system of additional professional education. To determine the areas of teachers' professional development it is necessary to identify individual and typical difficulties in their professional activities and, on this basis, develop an individual-differentiated educational route. It is an educational program that allows each teacher to choose areas of professional development, presented in the form of educational modules. This makes it possible to take into account requests from the education sector.

Individual blocks of an individually differentiated route are:

- professional development in the system of additional professional education;
- activities in the professional community;
- participation in methodological work;
- self-education and self-development.

The value of individually differentiated routes is that they are based on the reflectionprinciple and are accompanied by a constant adjustment to the content of educational modules. This approach to improve the teachers' professional competence allows not only to realize creative potential, but also to develop value orientations, develop individual technologies of pedagogical activity. In conclusion, we note that the composition of the competences mastered by teachers will determine the effectiveness of the Russian education sector and its competitiveness in the world market of educational services.

Discussion and Results

The success for achieving the goals of educational activity and its organizational and methodological support is largely determined by the level of teachers' professional competence as the main performers of the requirements by regulatory legal acts in the field of education.

Accumulating within an educational institution, human resources must be subordinated to a certain system that requires timely and clear management. We propose a block diagram of human resource management consisting of four subsystems-object, process, environment, and project. Building such a system requires careful work to determine the composition of teachers' competences that will improve the effectiveness of their activities.

The analysis of scientific works allowed us to state that the concept of "competence"is broader and more capacious than the concept of "competency": the first one "absorbs" the second one, which, in its turn, is the content of the educational process and forms the competence of the student. Competence is the final result of the education process, which is expressed in the student mastering skills of activity in various life situations.

Nowadays, not only employers, but also the academic community and the public are involved in forming the list of competences necessary for teachers to master. In turn, the development of a certain competenceset becomes the main goal and result for the success of the learning process. At the same time, the quality of the educational process is determined by the student's ability to apply the received information making decisions in standard and changing conditions.

Specialists and researchers in the field of management are trying to analyze comprehensivelythe problem of professional competence in the field of education. Their attention is drawn not only to the process of professional training, but also to the personal factors that determine the individual components ofteachers' professional competence.

Analysis of foreign and Russian sources has shown that at present a single semantic field for the emerging concept of professional competence has been developed. In general, we note that professional competence:

- refers to the personality of its bearer;
- it is not limited only to knowledge, skills and abilities, although it is manifested in them;
- it can develop and, accordingly, be diagnosed in the course of specially organized educational activities that imitate professional activity.

Having studied the existing theoretical and practical base, we can conclude that professional competence is understood as a combination of a teacher's professional competences, forming its level at a specific time. In turn, professional competence is a requirement for the teachers' educational training, which allows them to perform their labor functions effectively.

Individual elements of a teacher's professional competence can be found in various areas of their professional activity, such as:

- training;
- conflict prevention and resolution;
- communication;
- realization of action;
- analysis of problems;
- professional development.

A teacher having these competences conducts pedagogical researcheffectively and is able to build a program of his own professional development, identify difficulties that hinder this development, and learns constantlyby himself. Improving pedagogical competence is designed not only to help teachers overcome emerging professional difficulties. Its main goal is to form the professional readiness of teachers to implement Federal state educational standards in the educational process.

Abstract

The purpose of this article is to present the issues related to obtaining the information from available databases, to provide a definition of natural language (NL) and to identify the main tasks and challenges of NL processing (NLP), based on the available literature of artificial intelligence (AI). The following part of the article presents a short history of NLP, also points to existing basic methods by NL generation (NLG) systems and problems of the NL understanding system. Then, the methods of visualization and data mining techniques were indicated, and the summary gave the areas of application (including machine translation).

Keywords: Natural Language, Artificial Intelligence, Cognitive Science, Data Mining

Introduction

Artificial intelligence it is no longer science fiction for us. It is present every day and everywhere - starting from applications such as marking photos on FB or converting speech to text, machine translation through online fraud detection, to breakthrough solutions in medicine, such as predicting injuries or the most modern autonomous cars.

More and more common data storage in the so-called "Cloud", decreasing costs of data processing and ubiquitous access to the Internet - this causes the generation of millions of terabytes of data every day, possibility of analyzing and drawing conclusions, creates opportunities for development. Cognitive technologies play a huge role as tools helping to extract information on the basis of analysis with the use of algorithms.

Cognitive systems (CS) make it possible to organize and manage this huge amount of information/data. These systems can be programmed for the so-called "Independent learning and prediction" which information may be of interest to a recipient.

CS include following data processing methods: data analysis, NL processing, machine learning. One of the main tasks of cognitive software is to support interpersonal communication and decision-making processes by ensuring greater accuracy and speed. By processing data from various sources and reports, CS support decision-making in management[1], support process management through "Workflow".
The most dynamically developing machine learning techniques, used in business, shows that AI has settled in our lives for good.

Machine learning (ML), including one of its varieties - deep learning is a key method of extending the area of artificial intelligence applications. ML is creating such programs that make inference, planning, prediction, and remembering based on algorithms managing series of big data, so the system is able to make the most optimal/rational decision.

It should be remembered that the role of man does not remain eliminated, he should supervise the course of the process and prevent it in non-standard situations.

The use of CS is basis of the Industry 4.0, which involves introducing innovation[2] by creating of a new product first in virtual reality, then in the real world, so it can be modeled, configured, tested and checked in accordance with the customer needs. It is possible to produce products in single quantities while remaining cost effective. It is not possible

without the use of integrated IT systems. Advanced cognitive technologies can process them. For data management is needed an infrastructure that mimics the operation of human brain, artificial neural networks (ANN).

Research on ANN began in neurophysiological and biocybernetic research. The first DNA model of a neuron was officially made by Warren McCulloch and Walter H. Pitts (1943). This description inspired later research into ANN.

Currently, ANNs are used in cognitive science to recognize images, patterns, sounds, speech, writing, data processing, forecasting and modeling various phenomena and processes. The universality of ANN allows to be effectively used in management, economy, finance, technology, medicine, geology, mathematics and computer science.

ANN are defined as combinations of elements called artificial neurons that make up at least three layers: input, hidden and output, with multiple hidden layers.

An important feature of the ANN model is its ability to learn and to generalize the acquired knowledge. Two basic types of learning can be distinguished:
- supervised learning ("teacher learning") consists of comparing the network output signal with the known correct answers. In this case, the human presents the correct answers and the ANN creates the structure of the neurons;
- unsupervised learning ("teacherless learning"): the network has to create its own categories based on dependencies in its input data in order to recognize the input signals.

"Training" of the ANN is a key element of its functioning. An excessively trained network may generalize the results too much, which means that its operation will be similar to classical algorithms. However an insufficiently trained network will make too many mistakes, making its usefulness negligible.[3]

Definition of NL

NL is understood in two ways. First, the concept of NL is used as a term to describe a language developed through the historical development of ethnic, national groups, as opposed to artificial languages.[4] Second, it is the language people use to communicate interpersonal, and the term is used in mathematical and technical disciplines, unlike formal languages (programming languages).[5]

NLP is an interdisciplinary field that combines the issues of artificial intelligence and linguistics. It deals with the automation of analysis, understanding, translation and NLG by the computer. NLP consists in transforming the information stored in a database into a language that is easy to read and understand by a human. In turn, a system that understands NL transforms it into formal symbols that are easier for computer programs to process.

NLP problems relate to language generation and comprehension. The morphological model of a sentence that a computer should build is necessary for the sentence to be understandable and grammatically correct. NLP overlaps with the field of computational linguistics and is considered a sub-division of AI. On the other hand, the term NL is used to distinguish human languages (English, German, Polish) from the formal language (computer language: C ++, Java et al.). While NL analysis (NLA) can deal with text and pronunciation, work on speech synthesis has developed as a separate section.

History of NLP

The history of computer understanding of text goes back to H. P. Luhn and concerns the automatic creation of literature summaries by IBM.[6]

Next, a project called 'Parseval / GEIG' compared the grammars of different languages with a phrase structure.[7] However, in the next project, "Tipster", series focused on tasks such as summarizing, translating and searching.[8] In 1994, the German markers were compared in the "Morpholympics" project in Germany. Then, the Senseval and Romanseval campaigns aimed at semantic clarification of meanings. In 1996, Sparkle's evaluation compared parsers in four languages (English, German, French, Italian).

A year later in France, the Grace project compared collections of 21 tags for the French language.[9] In 2004, during the project "Technolangue / Easy" 13 French parsers were compared.

Large-scale evaluation of dependent parsers took place in 2006 and 2007 on the occasion of joint assignments at the Conference on Computational Natural Language Learning. In 2007, an campaign was launched in Italy to compare

different tools for an Italian website of the same name. In France, during the ANR-Passage project (at the end of 2007), 10 French parsers were compared on the website (http://atoll.inria.fr/passage/)[11].

Depending on the assessment procedures, there are types of NLP assessment: internal/external; automatic/manual; assessment based on the principle of black box and glass box.

Internal evaluation examines a single NLP system and determines its performance based on standard scores which are predefined by the evaluators. External evaluation (in-use evaluation) examines the NLP system with complex settings, either as built-in or to perform functions for the user. External performance of the system is determined based on usability, taking into account the overall task assigned by the complex system/user.

Considering a parser that is based on the results of new part-of-speech tags, on internal evaluation, the part-of-speech tag is triggered with respect to the data and compares the system data obtained by the tag to the standard data. During external evaluation, the analyzer is started with a different part-of-speech tag, then a new tag, and then the accuracy of the analysis must be compared.

Automated procedures can be defined to evaluate the NLP system by comparing the results to a standard. The costs associated with the development of the standard itself can be quite high, the automatic evaluation can be repeated as often as needed without significant additional costs (with the same input). For many problems with NLP, setting a standard is a difficult task and may not be feasible when internal tag agreement is insufficient. Thus, manual assessment is performed by assessors responsible for the quality of system or the quality of the results generated by the system based on the criteria. The assessors may be regarded as a source of information on many tasks related to linguistic analysis due to their linguistic competence, there may also be discrepancies among their assessments. This is why automatic evaluation is considered an objective evaluation as people tend to be subjective.

Black box assessment involves running a NLP system on a database and measuring parameters related to the quality of the process: speed, reliability, resource use, quality of the result (accuracy of data determination, translation fidelity). Glass-based assessment involves checking the system design, introduced algorithms, used language resources (word count, etc.). Given the complexity of NLP-related problems, it is difficult to predict the performance of a system on the glass-based assessment box. This type of assessment provides information regarding the analysis of errors or the future direction of the system.

Existing basic methods in NLG

Since 2009, companies have been founded to build systems that transform data into narrative using NLG and AI techniques. These include Arria NLG, Automated Insights, Narrative Science, Wordsmith and Yseop, which are discussed in the article "Natural Language Generation in Artificial Intelligence" by Ilyas Khan.[12] The process of generating text through a sophisticated NLG system needs planning and information steps to enable the generation of text that looks natural and does not become repetitive. Common steps in generating a NL by NLG systems: from historical data; data comparison and making choices; content definition (deciding what information to include in the text); text structuring (organization of the information provided); aggregation (combining a sentence to improve legibility and naturalness); lexical choice (appropriate words and concepts); generating referencing phrases (making decisions about pronouns and other anaphora languages); execution (creating a new text that should be correct according to the syntax, morphology and spelling).

Tasks and challenges of NLP

NLA is way of "communicating with the computer". Initially, the world of scientists was overwhelmed with enthusiasm due to the work on simple word juxtapositions and in terms of limited language. However, enthusiasm quickly faded as the system collided with real situations, complexity and ambiguity of words or phrases.

The definition of understanding is a problem in NLA. Recognition of a NL requires a broad knowledge of the world and the ability to transform it. For this reason, understanding NL is called the AI-complete problem, which is that in order to understand the human world and language, AI should perceive it in the same way as humans.

In most spoken languages, sounds are presented as consecutive and juxtaposed letters. Converting an analog signal to symbols is a complicated process. In natural speech, there are few gaps between consecutive words. Where a break occurs depends on semantics and grammar of language, and context of a sentence.

Some languages (Japanese, Chinese, Thai) do not have word boundaries in the written language. Each syntactic analysis requires the marking of boundaries, which is a complicated challenge.

Many words have more than one meaning. In such situations is needed to choose the word or phrase that best fits the context.

The grammar of NL is ambiguous. There are many possibilities to parse a sentence. Choosing the best option requires information about the context, or semantics (meaning).

An obstacle may be a foreign/regional accent, a speech defect, errors in the text: typos and incorrect grammar, optical character recognition (OCR).

The interlocutor may perceive a sentence as stimulus for a reaction. The sentence structure may not contain information to identify this reaction. A question may be the sender's request for action by the recipient. This answer can be expressed verbally and through facial expressions or as mixture of both.
Question "Can you give me your name?" requires an answer (name). Instead, the question: "Can you pass me the flour?" it is a request for physical activity. The answer "Yes, I can" without the accompanying activity is not appropriate (although the answer "No" or "No, because it is finished" fully explains the lack of any activity).

When we consider longer sentences within the grammar of a NL, it turns out that most of them will not be unambiguous and will be able to be analyzed in many ways. To overcome such problems, statistical analysis of NL uses stochastic, probability and statistical methods. In such situations, use is made of language corpora (sets of texts for linguistic research: determining the frequency of occurrence of word forms, syntactic constructions, contexts in which words appear), or Markov chains (sequences of events in which the probability of an event depends on the outcome of the previous event)[13].

NLP uses available means to automate linguistic analysis, including probability models (n-gram model[14]), information theories and linear algebra. This technology is derived from machine learning and data analysis, which are branches of AI.

Programs supporting NLP, working with texts, information collections:

Anaphora Resolution (finds what an anaphora refers to in the text);
Automatic summarization (summarizes the text containing the most important information);
Foreign language reading aid (helps in reading foreign language);
Foreign language writing aid (supports writing in foreign language);
Information Extraction (IE) (analyzes unstructured text in order to extract information, facts from documents and the user analyzes them);
Information Retrieval (IR) (collects/retrieves information)[15];
Named Entity Recognition (NER) (is part of IE, it indicates which words in the text are proper names; in some languages not only proper names are written in capital letters, but also all nouns, such as in German);
Natural language generation (NLG) (translates data from computer language into NL);
Natural language understanding (deals with the understanding of NL by computer);
OCR (software for recognizing graphic characters from scanned text);
Question answering (answers questions using NL: questions with one answer, such as "What city is the capital of Poland?" or with many such as "What is the meaning of life?");
Speech recognition (can save the text of a conversation from an audio file, it is the inverse of text-to-speech processing, the inverse of speech synthesis, an operation consisting in processing text into speech);
Spoken dialogue system (recognizes speech and has a speech synthesis module);
Text simplification (software that simplifies grammar and structure of the text).

We should mention various types of computer translators-programs that automatically (machine) translate text from one language to another, as well as commonly used software that corrects the text, that is, marks errors in written text.

Problems of the NL understanding system

It is impossible to transcribe a spoken language completely without human intervention. This takes place, during the preparation of transcripts of conversations, discussions, when, people speak simultaneously. In such situations, programs "get lost" and are not able to reflect the meaning of the dialogue. Of course, people who deal with this type

of translation use the software, but they have to correct the written text to convey the meaning for example, when translating conversations shared on YouTube channels.

Sentences like "They gave the animals fruit because they were hungry" and "They gave the animals fruit because they were old" have the same grammatical structure. The verb "were" is used in first sentence to refer to animals and the other to fruit. Without knowledge of a situation, it is impossible to say in which case the verb "were" refers to which noun. Such a string of words can be interpreted differently.

The known English phrase "Time flies like an arrow" can be understood in several ways: First, it may be the traditional comparison that time flies so fast like an arrow. The word "flies" in English also means flying insects, and the noun "time" can also be a verb. The meaning of the expression above can be interpreted: "(You should) time flies as you would (time) an arrow" (the expression is read in the imperative). With this assumption regarding the meaning of the words "time" and "flies", the analyzed statement can be understood as "Time flies in the same way that an arrow would (time them)".

Another meaning relates to the comparison of flies and arrows: "Time those flies that are like arrows".
"Time-flies" can be read as kinds of flying insects, which in the sentence above would mean that all insects of this kind like a single arrow an apple or fruit flies like an apple).

"Time-flies" in the above sense can also mean that each type of flying insect likes a different arrow separately.

Another meaning may be that a specific object, such as a Time magazine, flies through the air in a manner similar to an arrow.

Analytical NLs, as modern English, which have practically no inflectional morphology to help distinguish between parts of speech, are demanding in this regard. In English and in some other languages, there is no indication of which word the adjective refers to. An example would be the phrase "cute little guinea pigs cage”.

Does "little" refer to "guinea pigs"?
Does "little" refer to "cage"?
Does "cute" refer to "guinea pigs"?
Does "cute" refer to "cage"?

In spoken language, information is suggested by accentuating individual words. Sentence "They never said he stole their money" shows how important the role of stress in a sentence is and how important the NL analyzer has to deal with when performing parsing. Depending on what word is stressed by the speaker, this sentence can have several different meanings:

"They never said he stole their money." They just didn't say it.
"They never said he stole their money." They just said that he probably only borrowed the money.
"They never said he stole their money." They might have suggested it in a different way, but they never said it directly.
"They never said he stole their money." They said he stole someone's money.
"They never said he stole their money." They said he stole something but not their money.
"They never said he stole their money." They said someone took their money, but they didn't say it was he.
"They never said he stole their money." Someone else said it, but not they.

The purpose of the efficient functioning of NLP is to measure one or more features of a given algorithm or system to determine whether and to what extent this system meets the assumptions of its creators and whether it meets the needs of its users. Research on the evaluation of NLP is currently popular, because determining the evaluation criterion remains the way to precisely define contemporary NLP problems beyond the general nature of tasks defined as understanding or generating language without additional human intervention. The set of evaluation criteria, which includes its data and metrics, allows to compare the solutions for a NLP analysis problem.

Information retrieval and data mining techniques

Information retrieval may be understood as finding in a large collection of unstructured documents (expressed as NL text) that meet a information need. There are a number of applications of search systems: searching for legal acts, searching for books in a library, searching for websites.[16]

Data mining, data acquisition, data extraction, data mining is one of the steps in the process of obtaining knowledge from databases. The idea of data mining is to use the speed of a computer to find hidden (because of the limited time possibilities) regularities in the data stored in databases.

There are many data mining techniques that come from well-established fields of science: statistics (statistical multivariate analysis), machine learning.

Techniques, methods for data mining derive from the field of AI research. The examples of applied solutions: evolutionary methods, fuzzy logic, machine learning methods, neural networks, rough sets, statistical methods, visualizations on charts.

In data mining, processing methods are developed, plants are tabulated, using banded algorithms, and the results presentation mode: classification, grouping, qualitative data analysis, quantitative data analysis, searching for associations, summaries.

There are areas of data mining application, where information systems are used to collect the obtained data in the form of databases. Due to the simplicity of database construction and acceptable prices, data collection systems are used in all areas of life. Wherever a database exists, there is a need to analyze this data in order to discover unknown knowledge. Fields in which data mining is widely used are astronomy, economics, medicine, technology, business etc.

„Knowledge Discovery in Databases (KDD) refers to the broad process of finding knowledge in data, and emphasizes the "high-level" application of particular data mining methods. It is of interest to researchers in machine learning, pattern recognition, databases, statistics, AI, knowledge acquisition for expert systems, data visualization.

[...G]oal of the KDD process is to extract knowledge from data in the context of large databases.

It does this by using data mining methods (algorithms) to extract (identify) what is deemed knowledge, according to the specifications of measures and thresholds, using a database along with any required preprocessing, subsampling and transformations of that database."[17]

KDD is used for: analysis of banking operations, creating targeted advertisements, credit risk assessment, customer segmentation, designing a data warehouse, fraud detection, genetic research, internet traffic data mining, recognition of image, speech and handwriting signals, sales forecasting, supporting medical diagnostics.

An example is extraction of a dependency in the sales data of a product, consisting in the fact that customers who have purchased a product usually buy other specific products.

Examples of data visualization: box plots, the aim of which is to visualize the properties of features in order to select variables that are characterized by the greatest shifts in quantiles, maximum and minimum values and medians; charts of empirical distributions for selected variables; histograms for selected predictive variables.

Following data can be read from the charts: density, feature value, frequency, maximum, median, minimum, mutual correlation of variables, number, quartile.

Summary

Today's translations are promoted by modern programs to support the translation process. Machine translation systems are applications or online services that use machine learning technologies to translate large amounts of text from and into one of their supported languages. The service translates a "source" text from one language into another "target language".

Concepts behind machine translation technology and the interfaces to use it are simple, the science and technology behind them are extremely complex and bring together several cutting-edge technologies: deep learning (AI), big data, linguistics, cloud computing and web APIs.

Since the early 2010s AI technology, deep neural networks (deep learning) has enabled speech recognition technology to achieve a level of quality that has enabled the Microsoft Translator team to introduce speech recognition with its text translation technology language translation technology.

Historically, the machine learning technique used in the industry has been statistical machine translation (SMT). SMT uses advanced statistical analysis to estimate the best possible translations for word that is in the context of a few words. SMT has been used by all major translation service providers, including Microsoft, since the mid-2000s.

The advent of neural machine translation (NMT) led to a radical change in translation technology, which led to a higher quality of translation. This translation technology started for users and developers in 2016.

Both SMT and NMT translation technologies have two common elements: Require large amounts by human translated content (up to millions of translated sentences) to train the systems; they do not act as bilingual dictionaries, but translate words based on a list of potential translations based on the context of word used in a sentence.

In conclusion, because artificial intelligence is a very important topic, especially in the time of the COVID-19 pandemic, it should be said that the article is the basis for further considerations and research in subsequent publications.

Feature Inspection and Elimination in The Context of Breast Cancer Prediction

Arpad Kerestely

Transilvania University, Mathematics and Informatics Faculty, Brasov, Romania
arpad.kerestely@unitbv.ro

Abstract

Breast cancer is one of the world's most notorious cancer types for women, and together with the rest of the cancer types it forms the world's second most lethal disease for humans (Siegel, et al., 2020). Much research effort has been put into predicting and even preventing it. While the field of cancer prediction greatly benefited from machine learning in the past decades as many research papers addressed the problem of cancer prediction, there is still space for improvement. This paper aims to review some of the existent researches from the field of breast cancer, gather a set of useful methods and processes, and finally apply them on a publicly available breast cancer dataset, with a focus on understanding how different features, or their absence, can influence the outcome of a prediction.

Keywords: machine learning, feature extraction, breast cancer, classification.

Introduction

A big part of the research in healthcare focuses on cancer prevention, prediction and prognosis as stated by the authors in (Kerestely, et al., 2018). According to (Siegel, et al., 2020), "cancer is a major public health problem worldwide and is the second leading cause of death in the United States ... in 2020, 1,806,590 new cancer cases and 606,520 cancer deaths are projected to occur in the United States". The same research also states that the four leading cancers are: lung, colorectal, breast and prostate, split per gender as follows. 43% of the cancer cases in men are prostate, lung and colorectal, with prostate cancer accounting for more than one fifth of the new diagnoses. For women, breast cancer alone accounts for 30% of all the cases, followed by lung and colorectal cancers, totaling 50% of all the new diagnoses. "The lifetime probability of being diagnosed with invasive cancer is slightly higher for men (40.%) than for women (38.7\%)" (Siegel, et al., 2020). A study from (GLOBOCAN (Global Cancer Observatory), 2019) reported that in 2018 in Romania 83,461 new cases were detected, the most common cancers (listed in descending order) being: lung, colorectal, breast, prostate and bladder cancer. For men the most common being lung, colorectal and prostate cancer, while for women, breast with 25.1% followed by colorectal and cervix uteri cancers.

Having an obvious need for more research and understanding in the field of cancer prediction, the rest of this paper aims to: examine some of the related work regarding breast cancer datasets in section 2, followed by experimental results and discussions on the Netherlands Cancer Institute (NKI) Breast Cancer dataset (Ramanan, 2017) in section 3, and finally drawing the conclusions in section 4.

Summary of recent breast cancer researches

Breast cancer is one of the most invasive and dangerous cancers among women as it can be seen in (Siegel, et al., 2020) and (GLOBOCAN (Global Cancer Observatory), 2019), thus it draws the attention of many researchers. In the past few decades, it has been a topic that has seen improvements partially because of the newer machine learning algorithms. Still there is space for improving even more. As machine learning requires data to learn from, the speed at which this improvement is progressing is strongly dependent on the amount of publicly available datasets. Unluckily, and mostly because of the recent data privacy concerns, not much data is publicly available, and even less of it is new, so a researcher either uses what is publicly available, or teams up with a medical institute. In the case of this paper, the focus will be on researches that are done on publicly available data, so that the reported results can be verified and in a case-by-case scenario, improved.

A recent study of the breast cancer by the authors of (Al-Shargabi & Al-Shami, 2019) reports that on the Wisconsin Diagnostic Breast Cancer (WDBC) they achieved nearly perfect accuracy with the K-Nearest Neighbor (KNN), Random Forest (RF) and Multilayer Perceptron (MLP) algorithms. Besides accuracy, they also measured precision, recall, f-measure and ROC Area. While not mentioned by the authors, after trying to reproduce the results, it was

Cite this Article as: Arpad Kerestely "Feature Inspection and Elimination in The Context of Breast Cancer Prediction" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

discovered that in their experiments, the validation of the results was most probably done on the same dataset as the training, hence the very high accuracy. Still, this means that the mentioned algorithms were able perfectly learn the training set. It is worth mentioning that because the WDBC dataset is not balanced, the accuracy metric is not the best choice to measure the performance of different algorithms, still, the authors provided other, more relevant types of measurements for unbalanced datasets to support their results. An interesting preprocessing step that the authors made was an automatic feature selection, provided by Weka, with which they selected only four features out of the 31 existing ones, thus reducing dimensionality while preserving the prediction quality. The four selected features were: texture_mean, concave points_mean, Radius_worst, Smoothness_worst.

In (Agarap, 2018) the author studied multiple ML algorithms: GRU-SVM, Linear Regression, Multilayer Perceptron (MLP), K-Nearest Neighbor (KNN) search, Softmax Regression, and Support Vector Machine (SVM) on the same WDBC dataset. Prior to running the ML algorithms, they did a preprocessing step to standardize the dataset, namely the StandardScaler from scikit-learn (Pedregosa, et al., 2011). The initial dataset was partitioned in 70% training and 30% testing sets, and every tested algorithm performed with over 90% accuracy on the test set, with MLP reaching an accuracy of 99.04%. The author of (Agarap, 2018) noted that the success of these algorithms is based on the fact that the dataset is linearly separable, showing that the features are also linearly separable when inspecting them visually, one by one, on a 2D plot. This explains why algorithms like Linear Regression or SVM achieved good scores. Finally, the author points out that the results could be made more accurate if some sort of cross validation were to be applied, and the model's performance could be pushed even further if the optimal hyper-parameters were to be found. The author did not report any other metric besides accuracy, although the dataset is unbalanced.

Often cancer is a recurring disease but few dataset or even research papers address this issue, as stated by the authors of (Abreu, et al., 2016). Their study also gathers a list of used breast cancer datasets, out of which only four are publicly available (two from the UCI Repository). Furthermore, the authors collected data cleaning and preprocessing methods: normalization/standardization of data and missing data handling. Moreover, they gathered, described and grouped 16 of the ML algorithms in two categories, white-boxed and black-boxed ones, which are essential when trying to describe to a doctor, why and how did an algorithm find a particular result. They note that for small datasets the Leave-One-Out (LOO) is the best sampling strategy, providing small bias at the cost of higher variance. From evaluation metrics point of view, they note that for imbalanced datasets the accuracy metric may not be the best choice, while F-measure (if we are interested in the true positives mostly) or Cohen's kappa (if we are interested in the true negatives also) may be a better choice. Many of the papers reviewed by the authors of (Abreu, et al., 2016) used the help of medical experts to determine the relevant features of their dataset. This manual labor can be acceptable until some extent (if available) but can also prevent the ML algorithms to bring contribution to the medical field, as sometimes important information may be hidden in features not considered by the doctors.

The authors of (Lum, et al., 2013) took a somewhat different approach than the already mentioned papers. They used topological data analysis (TDA) on the Netherlands Cancer Institute (NKI) Breast Cancer dataset, to gather information from more than 1500 gene expression features. Their research provided interesting insights about the data by visually inspecting the resulting graphs. They report that the visual representations contain the same characteristics even if the dataset changes. Moreover, they reported finding some of the most important features that could determine the survivability of a patient, one of which they reported to be the ESR1 gene.

Experiments and Discussions

From the studied papers and from the careful searching on various public dataset repositories (UCI, n.d.) (data.world, n.d.) (opendatasoft, n.d.) (kaggle, n.d.) it was discovered that there are few publicly available datasets about breast cancer. Among these, the WDBC dataset is the most commonly used, providing 32 features of 569 patients. Published in 1995, it's a reasonably small dataset. Unfortunately, the other datasets are not too large either, some also have missing values. One particular dataset, compiled by the Netherlands Cancer Institute (NKI), while containing only 272 breast cancer patient records, has an impressive amount of 1570 features. This section aims to experiment on, and discover interesting knowledge in the afore mentioned dataset, by using the acquired knowledge from the reviewed papers. This knowledge mainly consists of: exploratory analysis, clustering, preprocessing, feature selection, partitioning, classification, evaluation of learning models and cross validation.

The Netherlands Cancer Institute (NKI) Breast Cancer Data was downloaded from (Ramanan, 2017). It contains demographic and clinical data about the patients and gene expression (genomic) data from breast tumors, that add up to 1570 features. The "eventdeath" feature gives information on which cancer cases were fatal. As it can be seen in Figure 1, the class distribution is unbalanced, which requires carefully choosing the scoring metric later on.

Figure 1*:* Mortality rate in the NKI Breast Cancer Dataset.

As a starting point, the "eventdeath" feature was extracted as the dependent variable. Next, the first two features, "Patient" and "ID" were manually removed, as those clearly represented irrelevant patient information (see Figure 2).

	Patient	ID
0	s122	18
1	s123	19
2	s124	20
3	s125	21
4	s126	22

Figure 2: Irrelevant patient information

Figure 2: Class separability of 13 features.

With the next 13 features which looked like clinical data, a class separability was visually checked, reducing the 13 dimension to a two dimensional space using RadViz (Daniels, et al., 2012) (see Figure 2). It turned out that there is an existing separation between the classes, which raised the curiosity whether a linear classifier could already perform well on just this small subset of data.

Therefore, the data was randomly subsampled, while keeping the class distribution: 70% for training and 30% for testing. A logistic regression classifier was trained on the learning sample, while the evaluation of the classifier was done on the testing sample, resulting in a 90% accuracy and 0.81 f1 score. From the confusion matrix (see Figure 3) it can be observed that there is a small number of False Negatives (FN) and False Positives (FP), 5 and 3 respectively. Although the number of FNs is low, in the cancer prediction domain the tendency should be to eliminate them all.

By having pretty good results with the current classifier, it is interesting to see how the features correlate to each other and to the dependent variable. The Pearson correlation score was computed between pairs of features, and the results

Figure 4: Pearson correlation between 14 features.

Figure 3: Confusion matrix for logistic regression classifier on the 13-feature dataset.

were color coded in order to be able to better visualize which two features correlate the most. In Figure 4 dark blue and dark red mean strong correlation, while light colors and white mean loose, or no correlation at all. Thus, it can be said that "timerecurrence" and "survival" have a strong positive correlation, while it can also be said that the "eventdeath" of a patient is influenced negatively to some extent by the "timerecurrence".

Looking at the whole dataset, it sounded interesting to automatically select the most n correlated features to the dependent variable. After a few tests it turned out that n was not easy to determine, and that the classifier's performance hardly improved. It was clear that another method of automatic feature selection was needed in lack of medical experts, who could have otherwise helped in determining the important features. Running the logistic regression on the full dataset, resulted in an accuracy of 86.58% and an f1 score of 0.75.

Scikit-learn (Pedregosa, et al., 2011) provides multiple ways of eliminating features. Among them, "Recursive feature elimination with cross-validation" provided a nice solution for determining the optimal number of features that would give the highest possible score. It can be seen in Figure 6, that the accuracy and f1 scores increases with the addition of every new feature until a number of 70 features is reached. After that it fluctuates, but never reaches a higher score. Running a logistic regression classification on a dataset containing only the 70 best features results in an accuracy of 96.34% and an f1 score of 0.93. Thus selecting 70 of the 1569 features results in both a faster and a more precise classification.

Figure 6: Logistic regression accuracy and f1 score with regards to the number of features.

Figure 5: Random Forest f1 score with regards to the number of features.

Running the same recursive feature elimination using a Random Forest classifier provides yet more interesting knowledge about the data and the different kinds of classifiers. Running the RF classifier on the whole dataset provides on average an f1 score of 0.4. Although the RF classifier already has an internal feature selection mechanism, after the feature elimination step used above for the Logistic Regression, the Random Forest classifier stops improving after the 15th most important feature (as it can be seen in Figure 5), even more, it keeps getting lower precision as the number of features grow. With the 15 most important features, it reports an f1 score of 0.87.

Conclusions

The experiments conducted in this research paper show the importance of analyzing and extracting every piece of information a dataset has to offer. Often something as trivial as visualizing the data in a two-dimensional space or examining the correlation between multiple features can uncover interesting facts about a dataset. Other time, eliminating some features or selecting ones over the others, using dedicated algorithms, can shorten the training time

or even improve the prediction score of a classifier. While the chosen classifier does matter, it proved, that a careful preprocessing can greatly influence the tides in the favor of better results.

Considering the reviewed research papers and the different issues encountered during the experiments, the following aspects should also be considered when engaging in a cancer prediction problem. Often, we want to know the malign and benign cases, or recurrence or no recurrence, so generally speaking, most of the time we will have a binary classification. The accuracy should only be used as a metric if the dataset is balanced. Furthermore, the accuracy can mean two things: the patient is either detected as having cancer so a treatment can be administered as soon as possible, or the patient is free of cancer, meaning that no further investigations or administration of treatment is necessary. If the dataset is unbalanced as it is usually in cancer prediction datasets, the f1 score, precision and recall should be used instead. Most often it is best to tune the algorithm so to fully avoid false negatives, because if not done so, it will lead to bad consequences. On the other hand, false positives should be minimized in order to reduce the costs of medical investigations and treatment. In cancer prediction data is often noisy, because of some points that were badly input so these need to be detected and sometimes even manually removed. Finally, algorithms which cannot be easily interpreted or explained to a doctor, could be rejected, so if possible, simpler, white-boxed algorithms should be chosen.

Top Management Teams and Human Resource Management Effectiveness

Magdalena MAJOWSKA

University of Economics, Katowice, Poland, magdalena.majowska@uekat.pl

Abstract

Attempts at solving the mystery of organizational success have resulted in many studies combining the concept of effectiveness and human resources management (HRM) perspective. It is showed in the literature that gaining a competitive advantage by the organization becomes possible through effective management of human resources. Moreover, the research also indicates that top managers believes and values affect effective HRM system designing and implementation in the organization. Taking into consideration the important role of top managers in making strategic HR decisions and the significance of HRM effectiveness for organizational outcomes, this theoretical paper has two main goals. First goal is to discuss two top management team characteristics: (1) an emphasis on strategic HRM and (2) the capability to manage resource vulnerability as being essential for improving HRM effectiveness. Second goal is to describe the concept of human resource management effectiveness as an antecedents for achieving organizational performance. All theoretical considerations are embedded in resource-based theory and upper echelon perspective which are then referred to the strategic HRM field. In consequence, some theoretical propositions that need to be empirically tested are presented. With these propositions should be possible to stimulate empirical research on HRM effectiveness by answering the question: Do the demographics and characteristics of top management teams matter for HRM effectiveness and, consequently, for organizational performance?

Keywords: Strategic Human Resource Management, Top Management Teams, HRM Effectiveness.

Introduction

Organizational performance, although widely discussed, remains one of the ambiguous issues of management studies. There have been numerous perspectives and various research approaches explaining the organizational success dilemma. This paper assumes that explaining the difference between firms that achieve or not achieve sustainable performance can be done by focusing on the effects of top management teams (TMT) on human resource management (HRM) effectiveness, which in turn influence organizational outcomes. Thus, this article aims to answer the following question: how important are TMT characteristics for HRM effectiveness and consequently for the organizational performance?

On the one hand, a significant amount of studies show that top managers play a fundamental role in influencing firm performance. As noted by Pitcher and Smith (2001, p. 1), '[t]here are few more important subjects to strategy scholars, or for that matter to practitioners, than the link between the people at the strategic apex of the organization and that organization's performance. 'This reasoning is consistent with the literature that is largely based on upper echelons theory (UET) and examines the individuals responsible for the organization, focusing on what they do, and how they do it (Hambrick, 1989; Hambrick & Mason, 1984). The specific attributes of TMT as central decision makers, will influence their individual problem framing, values and biases and, in turn, affect the decision-making processes (Carpenter & Reilly, 2006), including HRM decisions.

On the other hand, support from top management can facilitate the designing and implementation of various HRM policies and practices (Chadwick, Super, & Kwon, 2015; Fenton-O'Creevy, 2001; Hutchinson & Purcell, 2010; Stanton, Young, Bartram, & Leggat, 2010). As the main decision-maker in an organization, top management's beliefs and attitudes towards the HRM activities may also shape HRM effectiveness (Boada-Cuerva, Trullen, & Valverde, 2019). However, empirical research related to TMT and HRM are limited (Steffensen, Ellen III, Wang, Ferris, 2019). Many of these studies considered TMT as the targets of HRM activities (e.g., with executive-focused HRM systems), rather than focused on the roles that TMT played in shaping HRM policies and practices. Research about the role of

Cite this Article as: Magdalena MAJOWSKA "Top Management Teams and Human Resource Management Effectiveness" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

top management in managing people is relatively scarce. Therefore, there is great potential in addressing the effects of TMT on HRM field (Beer, Boselie, & Brewster, 2015).
Moreover, research on HRM should focus on the notion of „HRM effectiveness". The literature shows that it is not the quantity but the quality of the HRM policies and practices that matters. A simple number of best practices does not show whether these activities make sense in terms of the organization's policy and strategy or whether the resources have been used in an effective manner. This is the reason why Huselid et al. (1997) state that future research should go beyond the presence of HRM policies and practices to examining the effectiveness of these activities compared to the desired outcome. Guest and Conway (2011) confirmed that the effectiveness of HR practices is more important than the presence of practices in determining outcomes, suggesting that future studies should focus on the issue of HRM effectiveness.

To summarize, the notion of HRM effectiveness is discussed in this theoretical paper in context of maximizing organizational performance. Two TMT characteristics are indicated as being essential for achieving high HRM effectiveness: (1) TMT emphasis on SHRM and (2) capability of managing resource vulnerability. Presented propositions are embedded in RBT and UET and will serve as a starting point for planned empirical research.

The concept of HRM effectiveness and the possible ways of measure it

The SHRM perspective is focused on the importance of HRM function for organizational performance. The fundamental assumption in this field of research is to treat human resources as a critical resource in the strategic management process. However, to provide a source of competitive advantage organizations should manage their human resources effectively (Barney & Wright, 1998). Effective HRM can be described as an important catalyst in accomplishing strategic goals because can help attract and retain qualified human resources, motivate people for better work, develop the skills and competencies of employees, and create firm value through the selection, development and use of human capital (Lepak & Snell, 1999).

HRM effectiveness is a broad construct, described in different ways. Generally, this notion demonstrates HRM effectiveness as being a level of 'human resource management satisfaction with various human resource activities ' (Huselid et al., 1997). It refers to 'the value of what HR professionals do for the rest of the organization, and how HRM practices are linked to desired organizational outcomes '(Rule, Bondarouk, & Van der Velde, 2007). More specifically, HRM effectiveness may be characterized 'as the extent to which the operations manager felt that the department performed well, met his or her expectations, and was a value added/bottom line contributor to the business ' (Wright, McMahan, McCormick, & Sherman, 1998).

This notion has been operationalized in the literature in different ways. To indicate HRM effectiveness, HRM literature uses different performance measures, like financial measures, employee satisfaction, turnover and absence rates, and commitment (Obeidat, 2016). The operationalization of HRM effectiveness can be focused both on the effectiveness of HR policies as well as the effectiveness of HR practices. Some researchers (e.g. Tsui, 1987) measuring HRM effectiveness incorporate ideas from the organizational effectiveness literature, while others emphasize the evaluation of personnel management activities (e.g. Cascio, 1991; Teo, 2002). Most of them agree that measuring HRM effectiveness differs from traditional assessments that imply ask respondents to indicate the existence or non-existence of specific HRM policies and practices and move towards asking managers whether they believe that these activities are performing effectively. From that perspective HRM effectiveness can be measured by „the degree of fit between HR systems and the firm's business intentions with the ultimate criterion of the extent to which the firm has met its business objectives" (Tsui, 1987, p. 36). For the HRM system to be effective, it should meet also the needs and demands of its different groups of stakeholders.

Widely known questionnaire for evaluation of HRM effectiveness was prepared by Huselid et al. (1997). This tool examines perceptions of how well the HRM function is performing and includes two types of effectiveness: (1) technical HRM effectiveness which involves using traditional HRM practices such as recruiting, training, performance appraisal, compensation, employee relationships, and health and safety, efficiently, (2) strategic HRM effectiveness, which involves building human resource complexities through innovations such as team-based job designs, career management, flexible workforces and employee empowerment. In other words, technical HRM effectiveness describes 'how well the operational HR activities are performed', whereas strategic one describes 'perceptions of how well the HRM function developed a fírm's employees to support its business needs '(Huselid et al., 1997:175). In contrast to technical, strategic HRM activities are considered as HRM innovations by companies.

Cited classification introduced by Huselid et al. (1997) has been applied in further research on HRM effectiveness (e.g. Richard & Johnson, 2001, 2004; Wang & Shyu, 2008, 2009; Ryu & Kim, 2013). In many of these studies the

quality of HRM is measured by assessing the HRM policies and practices that an organization has in place (Chang, 2005; Huselid et al., 1997; Wright, Mcmahon, Snell, & Gerhart, 2001) rather than the effectiveness of their implementation (Bos-Nehles, Van Riemsdijk, & Looise, 2013). The presence of effective HRM policies and practices constitute a first and essential prerequisite to their effective implementation, it does not mean that HRM effectiveness depends only on the presence of good or ideal HRM activity. The context in which these HRM policies and practices are applied also plays an important role (Han, Chou, Chao, & Wright, 2006). Even if the intended HRM policies and practices are well designed, they can be ineffective if they are not properly and successfully implemented (Bos-Nehles, Van Riemsdijk, & Looise, 2013).

Thus, some researchers (e.g. Khilji & Wang, 2006) have distinguished between intended and implemented HRM policies and practices while describing the effectiveness of them. This differentiation lead to the conclusion that there are three major components of HRM effectiveness (Guest & Conway, 2011): (1) the existence of HRM policies and practices - they must be present in the organization; (2) the assessment of HRM policies and practices - they must be evaluated as effective and satisfactory; (3) the implementation of HRM policies and practices - they must be effectively implemented in the organization.

Successful implementation of HRM policies and practices remains a difficult process. Many organizations may adopt HRM policy or practice for institutional reasons, in contrast to those which are implemented competently to provide a dominant organizational force. Some managers may implement a given policy or practice simply because it represents the latest fashion or a fad rather than because the policy or practice is believed to work within the organizational context to achieve strategic goals. Research shows that the measure of HRM effectiveness gets at 'whether 'firms successfully implement HRM practices in a manner that actively affects firm performance (Arthur, Herdman, & Yang, 2016). The increase of HRM effectiveness is attributable to successful implementation of HRM policies and practices. However, there is little shared understanding as to how to achieve this effective implementation. Scholars proclaimed that when addressing the black box in SHRM research, it is especially critical to identify those capabilities that can facilitate strategy implementation (Becker & Huselid, 2006; Lin & Shih, 2008).

To sum up, organizations are still struggling with designing, implementing and using HRM policies and practices in an effective manner. Generally speaking, there is no broad understanding regarding the process that might enable firms to achieve higher levels of HRM effectiveness. The knowledge about the antecedents of the effective HRM policies and practices and the mechanisms which shape them remains relatively under-researched, leaving a number of issues unresolved. The presented logical arguments clearly make us pay attention to characteristics of top managers viewed as the context in which these HRM policies and practices are designed and implemented.

Two TMT characteristics that can be crucial for HRM activities

Some scholars have discussed the influence of top managers on the implementation of HRM policies and practices (e.g., Chadwick et al. 2015; Fenton-O'Creevy, 2001; Hutchinson & Purcell, 2010; Stanton et al., 2010). Top managers as organizational decision makers are usually discussed in paradigm of upper echelons (UE) which suggests positive relationships between a variety of TMT demographic indicators and firm outcomes (Finkelstein & Hambrick, 1996; Hambrick, 1989). Such demographics as 'age, functional background, and educational experiences are taken as observable proxies for the psychological constructs that shape the team's interpretation of the internal and external situation and facilitate formulation of appropriate strategic alternatives '(Carpenter, Sanders, & Geletkanycz, 2004). Popularity of TMT demographics is owed to – relatively easy – accessibility and measurability of demographic data. While TMT demographic variables are likely to remain an important part of upper echelons perspective research, it has already been pointed out in the literature that demographics have received substantial conceptual and empirical attention (Certo, Lester, Dalton, & Dalton, 2006).

Except from TMT demographics, there are some other additional attributes of a TMT that may be important factors in the determination of organizational outcomes. Carpenter et al., (2004) identified such attributes as: skills and orientations, social cognitions, behavioral propensities, access to resources and information, human and social capital and social status as being among the most important and significant characteristics of top managers. Unfortunately, these attributes have not been frequently analyzed in the UE research. It is the result of difficulties in collecting data from top managers. However, by measuring these features of TMT directly, rather than using demography-based proxies, it is possible to provide a glimpse inside the causal black box of UEP (Roh, H., Chun, K., Ryou, Y., & Son, J. 2019).

Two characteristics of TMT may in particular influence HRM effectiveness. They are: (1) TMT emphasis on SHRM and (2) TMT capability of managing resource vulnerability. Both of these notions refer to UE theory in their focus

on TMT and they stem from RBT, treating employees as the source of sustained competitive advantage. The empirical results suggest that the way an organization manages its human resources has a significant relationship with the organization's results (De Saá-Pérez & García-Falcón, 2002).

First characteristic - TMT emphasis on SHRM - results from the assumption that TMT having the appropriate perspective and attitude towards human resources increases likelihood of effective HRM (Arthur, Herdman, & Yang, 2014). The issue of managers' beliefs about the importance of HRM for an organization, although does not constitute a uniform and coherent structure, was discussed in the literature with to e.g.: management philosophy (Lepak, Taylor, Tekleab, Marrone, & Cohen, 2007, pp. 223-246), management logic (Chattopadhyay, Glick, Miller, & Huber, 1999, pp. 763-789) and values and beliefs (Bae & Lawler 2000, pp. 502-517). In many studies, this issue is identified with the selection of optimal criteria of action strongly correlated with the system of values professed by managers in the organization. Scarce research indicate that the top management emphasis on SHRM is a relatively capacious construct. Although not precisely defined, this concept has been operationalized by Chadwick, Super, and Kwon (2015), who propose to consider CEO's actions in the following areas: (1) praising employees for achieved challenging goals, (2), use fair procedures in HR practices, (3) adaptation of different kinds of HR practices that contribute to organizational performance; (4) spending much time on HR activities, (5) regarding the human resource department as a strategic partner; (6) viewing employees as a source of competitive advantage; and (7) putting much value in employees 'growth and well-being.

Second characteristic - TMT capability of managing resource vulnerability - results from the qualities of some resources that are purported on the one hand to generate rents, but on the other hand also may make them and their rents less sustainable, that is more vulnerable. Le Breton-Miller and Miller (2015) present three categories of manager's challenges. The first one is erosion manifested in three ways: (1) the superior value of a human resource which can give rise to rent appropriation, exit opportunities, or hubris; (2) the superior value of a sub-unit, which can skew attention and rewards too narrowly and cause neglect of complementary units; and (3) path dependence in intangible resources such as brands and reputation that render them fragile to managerial missteps and difficult to resurrect. The second is the result of ambiguity which increases with: (1) the ambivalence of a resource due to its early stages of development or obvious drawbacks that can lead to its neglect; (2) the causal ambiguity of a resource whose source of value is difficult to comprehend and thus is difficult to replicate; (3) the tacitness of an intangible resource, which makes it difficult to codify, share, and manage. And finally, the third challenge comes from misalignment, which relates to (1) the context dependency of a resource that makes it vulnerable to changes in its environment; (2) the systemic complexity of a resource that makes it vulnerable to its weakest link. In consequence, top managers need to manage resource vulnerability (i.e. to focus on the possibilities to sustain these strategic human resources) in context of: (1) protecting them from erosion, (2) coping with their ambiguity, and (3) preserving their required alignment. Le Breton-Miller and Miller (2015) propose several objectives to accomplish these goals: fostering loyalty, promoting equity, investing generously, identifying resources, parsing resources, codifying and sharing wisdom, matching resources and focusing and broadening capabilities. These initiatives are deeply rooted in the characteristics of strategic HRM and result from the necessity of helping an organization to ensure that its human resources are not easily imitated. Although the concept of Le Breton-Miller and Miller (2015) does not focus merely on human resources, it is assumed in this paper that their approach may be applicable *in extenso* to SHRM field.

Considering the above, it is proposed to treat (1) TMT emphasis on SHRM and (2) TMT capabilities of managing resource vulnerability as dimensions of TMT characteristics. Moreover, these two TMT characteristics are linked to each other in this way that the higher TMT emphasis on SHRM, the stronger should be the probability that TMT will have capabilities of managing vulnerability of human resources. Thus, it is supposed that:

Proposition 1: There is a relationship between TMT emphasis on SHRM and TMT capabilities of managing resource vulnerability

Two TMT characteristics as antecedents of HRM effectiveness

Two above-mentioned characteristics of TMT may influence HRM effectiveness. First characteristics of TMT - TMT emphasis on SHRM - can be crucial for HRM effectiveness for several reasons. First, some research indicated that the extent to which top managers view employees as strategic resources is positively related to the level of integration between the human resource function and strategic decision making (Bennett, Ketchen, & Schultz, 1998). Further, works by Noe, Hollenbeck, Gerhart, and Wright (1997), Butler, Ferris, and Napier (1991), Lado and Wilson (1994), and Bae and Lawler (2000) examined different types of links between HR managers and the firms' top executives, showing that top management making strategic decisions should consider human capital as a source of competitive advantage. Moreover, the notion of management values also reemerged in the discussion of the "architectural" perspective (Becker & Gerhart, 1996; Lepak & Snell, 1999), according to which the defining characteristic of an

HRM system is not the specific HRM policies and practices that are used, but rather the extent to which HRM policies and practices are consistent with an underlying philosophy or logic for managing people in organizations. Osterman (1994) confirmed that various factors, such as management values, explain variation in the adoption of "innovative work practices". In turn, Lepak et al. (2007) investigated the extent to which "high investment work practices" applied to employees were contingent on an "employee-centered HR philosophy." This philosophy variable reflected managers" 'general beliefs of high regard for employee welfare and treatment" (Lepak et al., 2007, p. 229). These authors found strong support for the hypothesis that HR philosophy predicted variation in the use of HR practices. Additionally, Chadwick's et al. (2015) study demonstrated that CEO emphasis on strategic HRM is a significant antecedent to commitment-based HR systems, and influences a firm's performance. Some empirical research linking the values or philosophy of top managers and the use of HRM policies and practices exists, but has been quite limited. It emphasizes not only the complexity of managerial emphasis on SHRM as a construct, but also the importance of its notion for both UEP literature and SHRM field, and thereby its relevance for strategic decision making in an organization. As a consequence, applying the issue of managers' beliefs about the importance of HRM for an organization to the UEP, i.e. referring this emphasis on SHRM to the whole TMT, it is supposed that:

Proposition 2: TMT emphasis on SHRM will positively influence HRM effectiveness

Second characteristics of TMT - capability of managing resource vulnerability - can also be crucial for HRM effectiveness. It is related to the fact that 'the social complexity and causal ambiguity inherent in strategic HRM practices such as team-based designs, empowerment, and the development of talent for the long term, competitors can neither easily copy these practices nor readily replicate the unique pool of human capital that such practices help to create '(Huselid et al., 1997, p. 173). In this situation, human resources become difficult to substitute, to add to getting features of being value and rare. Thus, top managers should possess some competences and capabilities that are linked to the knowledge of how to manage such resources which are able to generate rents, but also may make them and their rents more vulnerable. There is no research that relate to link between managing resource vulnerability and HRM effectiveness, yet there is some evidence that HR competences of executives and HR managers are a strong predictor of perceived HRM effectiveness (Han et al., 2006). Additionally, Huselid et. al., (1997) also evaluated the impact of HR managers' capabilities on HRM effectiveness and the latter's impact on corporate financial performance. Their results have showed that professional HRM capabilities and business-related capabilities increase the effectiveness of strategic HRM activities. Moreover, it can be expected that actions oriented toward providing resources characteristics mentioned by RBT (Barney, 1991) and described in the context of managing resource vulnerability by Le Breton-Miller and Miller (2015), give an organization the opportunity to achieve sustainable rents in the face of competition and may be treated as the value which is connected with HRM. Thus, it is proposed that:

Proposition 3: TMT capability of managing resource vulnerability will positively influence HRM effectiveness

Consequences of TMT characteristics and HRM effectiveness for organizational performance

The influence of TMT on organizational performance remains one of the most widely examined relationships in strategic management literature. On the one hand, most research reflects the importance ascribed by the academic community and in the business press to TMT demographics and characteristics (Certo et al., 2006). The theory of UE suggests positive relationships between a variety of TMT indicators and firm outcomes (Finkelstein & Hambrick, 1996; Hambrick, 1989). On the other hand, SHRM researchers have also reached an agreement on the importance of HRM effectiveness to organizational outcomes. The issue of how effective HRM policies and practices are linked to desired organizational outcomes is addressed in a great number of research (Boxall, 1996; Huselid, 1995; Ruel, Bondarouk, & Van der Velde, 2007; Wright et al., 2001). The empirical results confirm an association between more extensive use of HRM policies and practices and various indicators of organizational performance, such as productivity, employee turnover and financial performance (Teo, 2002). Overall, reviews of the human resource – performance relationship support the argument that firms with higher levels of HRM effectiveness experience performance gains (Boselie, Dietz, & Boon, 2005; Combs, Ketchen, Hall, & Liu, 2006).

Taking into consideration the influence of TMT demographics and characteristics (in UE theory) and HRM effectiveness (in SHRM field) on organizational outcomes it is assumed their reciprocal impact on organizational performance. However, it is posited that HRM effectiveness will acts as a mediator in this relation i.e. between TMT characteristics (TMT emphasis on SHRM and TMT capability of managing resource vulnerability) and organizational performance. Thus, it is proposed that:

Proposition 4: HRM effectiveness will mediate the influence of TMT emphasis on SHRM on organizational performance

Proposition 5: HRM effectiveness will mediate the influence of TMT capabilities of managing resource vulnerability on organizational performance

Conclusions

This article aims to answer the following question: how important are TMT characteristics for HRM effectiveness and consequently for the organizational performance? By answering the question this paper describes the nature of TMT itself as well as the influence of specific TMT characteristics on decision making processes represented by HRM effectiveness. Although these previous studies on TMT, HRM and organizational performance are very extensive and useful, they are limited because they rarely related to other attributes than TMT demographics that can explain HRM effectiveness; and, finally, did not evaluate the impact of TMT characteristics on HRM effectiveness and the latter's impact on organizational performance. Specifically, in this paper two elements of TMT members have been identified as important: (1) TMT emphasis on SHRM and (2) TMT capability of managing resource vulnerability. These TMT conceptual elements shall constitute a multidimensional construct referring to top management's attributes.

However, all proposals presented in this article are entirely theoretical and require empirical verification. It is intended by author to develop new measurement scale for TMT capabilities of managing resource vulnerability and adapt measurement scales of TMT emphasis on SHRM, HRM effectiveness and organizational performance. Within each company, it is planned to collect (1) one detailed HR questionnaire to measure HRM policies and practices from HR managers, (2) one detailed TMT questionnaire to measure TMT characteristics and firm perceived performance, and – if available - (3) secondary source records to measure financial performance. If possible, the number of questionnaires obtained from TMT will be increased to two. Thus, data from both multiple informants and sufficiently different TMT's increase applicable insights and statistical power for analyses (Lin & Shih, 2008). Behavioral analysis of the TMT meets its limits when it comes to the practical issues of conducting research. For instance, members of executive supervisory boards are usually hard-to reach respondents. Moreover, they are often reluctant to spend their time to participate in a survey bringing results which, they fear, might be used against them. In consequence, verification of any hypothesis regarding societal functioning of executive and supervisory boards becomes a challenge. Moreover, operationalization of the proposed concepts may be challenging. In particular developing new measurement scale for TMT capabilities of managing resource vulnerability and adapt measurement scales of TMT emphasis on SHRM is necessary. In addition, although the HRM effectiveness tool already exists in the SHRM literature, the conceptualization and measurement of HRM constructs is still a challenge. This is indicated by a literature review made by Boon et al (2019) which showed that „the increasingly broad conceptualization and measurement of HR systems and the lack of clarity on the HR systems construct at different levels have hampered research progress". Moreover, an analysis of measures of perceived HR practices showed that various problems and issues can be identified when critically reviewing these measures.

The intent of this paper is to reframe discussion concerning greater appreciation of organizational and environmental contingencies in which HRM effectiveness is embedded. Specifically, this paper and planned empirical research contains a set of objectives: (1) building knowledge about the nature and consequences of TMT conceptual attributes (demographics and characteristics); (2) adding TMT emphasis on SHRM and TMT capability of managing resource vulnerability as new constructs to SHRM toolbox; (3) contextualizing HRM effectiveness in regards to internal (TMT demographics and characteristics) and external environment.

Influence of Public Aid Coming from Self-Government Sector on Economic Development (Concept of The Research)

Magdalena KOGUT-JAWORSKA, PhD

University of Szczecin, Poland
magdalena.kogut-jaworska@usz.edu.pl

Introduction

Expectation concerning the public sector role are steadily growing. They concentrate not only on the traditional regulatory and stabilizing role of the state, but on the active participation as well. The expectations are aimed at creating proper conditions for economic development. Public aid is one of the tools applied in order to meet the goals set for public policies. Effectiveness of public aid application is a crucial issue, having in mind a high level of pressure on more economical expenditure of the means available. Secondly, public aid is always targeted at the chosen subjects, which has influence on the competition and on the market. However, it may also have negative impact on the market. Research on public aid effectiveness includes some elements of balancing the negative and positive elements of the aid application.

Keywords: Public Aid, Public Finance, Self-Government Finance Economic Development, Regional Policy

The goal of Research

Public aid can have at least three basic sources of financing; foreign means, public budget (e.g. state budget or self – government budget) and mixed sources. Public aid from self-government sector can have positive influence on economic development if it is targeted precisely at production growth, but it can have neutral (or even negative) impact if the aid is not connected with the economy. Although there exist some examples of ineffective public aid, it can be concluded that the aid targeted properly, will influence positively economic growth in the both, micro- and macro environment.

A broad research study on effects of public aid granted by the self-government sector will enable to verify the two following hypotheses:
H1 Public aid given by the self-government sector brings about positive and long – lasting effects for economic development.
H2 Public aid given by the self-government sector might be an infective tool of stimulating economic development.
Results of this research will enable to test auxiliary hypotheses which are as follows:
H1 Investment with participation of EU funds distributed by territorial governments improves economic efficiency of companies.
H2 Investment with participation of public funds from territorial self-government, not only influences positively competitiveness, but ensures long-lasting development of companies.

The main scientific aims of the research are to estimate the influence of public aid coming from the self-government sector on economic development, and to introduce and describe the prospects for proper functioning of public aid in the context of economic changes. Within the analysis of the impact of public aid transferred by the self-government sector, there will be made an attempt to define both: the well-developed and the underdeveloped (marginalized) areas, with particular reference to efficiency improvement dynamics of economic growth and unemployment reduction.

The particular research objectives are:

- formulating assessment methods in order to measure effectiveness of public aid coming from the self-government sector in Poland, with adequate attention paid to the conditioning of the process and having in mind potentially varying approaches to (the question) of effectiveness from the viewpoint of the public budget and on goals of economic development,

Cite this Article as: Magdalena KOGUT-JAWORSKA "Influence of Public Aid Coming from Self-Government Sector on Economic Development (Concept of The Research)" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

- formulating application procedures for particular instruments of public aid by units of self-government and creating complete solutions (model and procedures) related to an integrated mechanism of influencing economic decisions of the existing companies, as well as decision of potential investors (including the external ones),
- identification and assessment of the self-governmental support system within public aid, which will finally enable to create model solution of economic development at the local and regional levels.

Research Method

The following research methods will be applied to accomplish the above objectives: critical analysis of domestic and foreign literature, desk research method, scoring method (scoring applied and processed for the needs of this research), prediction method (based on time series with application of statistical methods.

Empiric research will be conducted to enable identification and assessment of influence of public aid coming from the self-government sub-sector on overall economic development. The main goal of the empiric analyses will be to identify the actual influence of public aid supplied by the territorial self-government on conditions in the economic sector. Empiric research (mainly surveys) will be conducted among representatives of self-governments and entrepreneurs in some chosen regions ("voivodships") in Poland.

Different levels of social and economic development of the regions will be indicated with the application of taxonomic methods, i.a. synthetic indicator of Z. Hellwig method, (the indicator will include such variables as unemployment rate, investment expenditure in companies, also in statistical subjects of the national economy registered in the REGON, an indicator of demographic load and gross value of fixed assets).

Influence of economic changes on application of public aid from the self-government sub-sector will be defined by application of probity models. The applied methodology will enable to assess statistical salience, as well as chances of occurrence of the phenomena in question according to changing phases of business cycle. The characteristic feature of probity regression is a possibility of precise assessment of parameters and the assessment of their salience for changeable variables expressed by binary.

When concentrating on the analysis of the two dimensions of effectiveness, i.e. the level of realization of economic objectives and the possibility of application of support instruments, there will appear a necessity to access information concerning public aid (data from the consumer and competition Protection Agency) and other information about companies, which is processed by the Main Statistical Office within its annual survey, as well as financial data from the Ministry of Finance and the regional tax offices. Data accessibility does condition to a large extent possibilities to recognize effectiveness of public aid. Moreover, accessibility of company financial data is also required in particular, the information about financial results taxes paid and public aid received.

Effects of study

It must be indicated that until now, there have not been defined theoretical and pragmatic bases which concentrate on the subject of public aid within territorial self-government.

Foregoing research concerns the broad concept of nationwide public aid (it needs to be mentioned that such approach to the subject concerns approximately three thousand of various institutions). Other studies are fragmentary and concentrate usually on a selected aspect of the local economy, e.g. local taxes. The literature lacks comprehensive studies concentrating on the level of territorial self-government. Such comprehensive approach to the subject of public aid should refer to the whole self-governmental budget policies, including instruments of both- active and passive character.

Its needs to be said that the necessity to prepare a study concerning public aid in the self-government sector is stressed by representatives of self-government practice. They indicate the necessity to conduct up-to-date analyses describing possibilities of influencing the sphere of economy through local forms of public aid. The analyses will also make it possible to formulate particular conclusions and recommendations within the scope mentioned. On the other hand, a study describing a system for stimulating local entrepreneurship would be a complete source of knowledge for business people who seek various forms of financial support for their companies.

Having considered the needs of self-government policies and having in mind some theoretical considerations, it has been concluded that the final stage of this research should work out effective forms of public aid application by self-government units, aimed at stimulating economic development and comprising both, the existing instruments as well as the potential ones – those expected by the business community. Moreover, the project should verify the existing

amount of knowledge about public aid in Poland and it should analyse comparatively the forms of public aid in Poland and abroad (in selected EU countries, featuring the structure of territorial self-government similar to the Polish model. The project will also assess the impact of various forms of public aid applied by the territorial self-government and it will analyse and verify the present solutions.

Abstract

The bilateral investment treaties (Bilateral Investment Treaty, BIT) are a signal delivered to investors by the host country. The effective condition of the signal lies in the difference of BIT compliance cost, so investors have the basis to distinguish different types of host countries. Based on Jan Peter Sasse analysis, the signal effect mechanism of the bilateral investment treaty is analyzed by using the signal model under incomplete information. The game between host country and investor is the signal transmission game of incomplete information. For both types of host countries, it is advantageous to sign a BIT. The host country adopts the strategy of "signing BIT" and makes a credible commitment of property right protection to investors through BIT. BIT gives the host country a competitive reputation advantage in attracting capital. Under the constraints of the investment agreement, investors can anticipate the behavior of the host country, and foreign investors are more inclined to invest in the signed or effective BIT countries. For investors, on the premise that the expected return of investors is positive, if the host country signs BIT, it will form a positive investment incentive for investors. When the expected return of the investor is zero, the investor can be considered as a potential investor (the investor may or may not invest). In this case, whether the host country "signs BIT" is more sensitive to the influence of the investor in judging the type of the host country.

Keywords: bilateral investment treaty, foreign direct investment, incomplete information, pooling equilibrium, separating equilibrium.

Introduction

Under the analysis framework of Sasse, its model assumptions were further relaxed. Based on the non-negative expected investment return of investors, this paper finds out the conditions for the bilateral investment treaty to be an effective signal. Due to the differences in BIT compliance costs, different types of host countries have different costs of sending BIT signals. Only host countries with superior investment environment will face smaller compliance costs, which provides investors with the basis to distinguish different types of host countries, and thus alleviates the time inconsistency problem to some extent.

Investors' investment activities in the host country have the characteristics of "time inconsistency (dynamic inconsistency)". Before and after the establishment of the investment project, the status between the investor and the host country is a reciprocal relationship. The fundamental reason for the status change between the investor and the host country before and after investment is that the information between the two parties is not fully and completely symmetrical. Based on the perspective of investors, investors are not sure which countries are "credible" of the host country (these countries actively "attracting foreign investment" and "cooperation" attitude, provide investors with a stable, predictable investment environment), which countries is "not reliable" of the host country (the country in various direct or indirect way erosion in the interests of the foreign investment in the project duration, not take the

attitude of "cooperation"), investors do not determine the real investment environment of host country, and the situation of the host country only its own has the most complete enough information.

In the process of summarizing and sorting out the literature on the relationship between bilateral investment agreements and foreign direct investment, it is found that many literatures put forward signal theory to explain the regulating effect of BIT on foreign direct investment in order to deal with the above time inconsistency problem. According to the signal theory, the signing of BIT between the host country and the home country to attract foreign capital to promote economic development is in essence to send a signal to the investors in the home country to promise stronger protection for investors, and at the same time to convey to other potential investors the real intention of restricting the government's improper intervention in foreign investment. According to the BIT signed by the host country, the investor weighs the country's willingness to protect the investor. According to the logic of signal theory, host governments that attract foreign investment formally communicate to investors the message of protecting domestic investment through BIT negotiation, signing and revision [2;3;4;5]. To send a credible and effective signal, the signatory countries need to pay the cost or have enough information support to identify the information of the host country providing investment protection and realizing investment liberalization commitment [6;7]. The more agreements signed by the host country, the stronger the positive signal will be, and the accumulated investment agreements will convey a stronger commitment signal of the host country, that is, to protect the investment environment of all foreign investment and to do a good job by themselves [8].

Formulation of the goals of the article

Sasse in signal model [10] and reputation model [11;12; 13], based on incomplete information game model, analyzed the signal effect mechanism of BIT. In the premise of Sasse [9] analysis, it is assumed that investors' expected return is negative before the host country sends a BIT signal. On this basis, this paper relaxes this condition to non-negative expected return of investors (that is, investors judge that the expected return of investments in different host countries is non-negative according to prior probability).This set because: first, for investors, if the investment is the key to whether the expected return is positive, if the expected return on investment is negative, which means investors prior probability is very low, that the situation is not very bullish on untrusted host countries, investment is not high, host by sending a BIT signal to attract investors investment motivation is not strong. Only when the expected return of investors is positive, investors will invest in the host country, and the host country will consider the issue of sending signals to attract investors. At this time, investors will further determine which are the real "Reliable" host countries and which are the imitation strategies of "Unreliable" host countries in the short term. Whether or not a BIT is signed by a host country does affect investors' judgment of the expected return on investment (investors regard "signing BIT" as a signal to judge the type of host country). Therefore, on the premise that the expected return of investors is positive, if the host country signs BIT, it will be more conducive for investors to make investment decisions. Second, the investors according to Bayesian rule updates its type of judgment for the host country or take a mixed strategy in the process of game, here is the premise of potential investors for at least two rounds of investment, which is regarded as the first round of investment investors expected investment strategy, only the expected return on investment is positive, investors would begin the next round of investment.

Results of the research

Reference Sasse analysis framework [9]: setting is "Reliable" Host Country (Hereinafter referred to as R) and "Unreliable" Host Country (Hereinafter referred to as U) and Multinational Enterprise investors (Hereinafter referred to as M) three rational participants represent.

Different types of host countries have complete information about their types." Credible" host countries actively "attract foreign investment" and adopt a "cooperative" attitude to provide a stable and predictable investment environment for investors; However, the "unreliable" host country does not attach importance to the long-term economic benefits and contributions of "attracting foreign investment" and undermines the interests of foreign investment in all kinds of direct or indirect ways based on short-term purposes or under the influence of external environment. During the duration of the project, it does not adopt the attitude of "cooperation". The situation of the host country is most complete only with information available to it. Some host countries also adopt the attitude of "cooperation" in order to actively invest foreign capital but conceal some imperfect investment environment in order to compete for foreign capital resources with other countries that "attract foreign investment".

Investors have incomplete information. Investors do not know the real type of the host country, investors are not sure about the real investment environment in the host country, and the situation of the host country is only the most complete information it has. Investors can only judge the type of host country according to Bayes' law based on whether the host country "signs BIT". The logic of adopting this criterion lies in that BIT, as a tool for information

provision and reputation construction, can enhance the credit of the host country. The positive impact of BIT on foreign investment is not spontaneous but depends on the host country's continuous compliance with the treaty and avoidance of international investment disputes [14]. For a credible host country, its real motive is "cooperation", so it is more willing to sign BIT to attract investors.
For both types of host countries, it is advantageous to sign a BIT. The host country adopts the strategy of "signing BIT" and makes a credible commitment of property right protection to investors through BIT. BIT gives the host country a competitive reputation advantage in attracting capital [15;16]. Under the constraints of the investment agreement, investors can anticipate the behavior of the host country, and foreign investors are more inclined to invest in the signed or effective BIT countries [17;18]. Among the factors influencing investors' expectations, whether the host country signs BIT is not decisive, but whether the host country signs BIT does affect investors' judgment on the expected return of investment. Assuming that the expected return of investors is positive, if the host country signs a BIT, it will be more conducive for investors to adopt investment strategies.

There are costs associated with a bilateral investment treaty. This includes two types of costs: the first type is the cost incurred by "negotiating and signing BIT", that is, the cost paid by the signatory countries during the negotiation process of the BIT and during the period from the signing of the BIT to the entry into force. There is no significant difference between "credible" and "untrustworthy" host countries in this category. Second, after the entry into force of a BIT, the performance cost of the host country's compliance with BIT and the reputational cost generated after the default, which is the key to distinguish "Reliable" host country from "Unreliable" host country. Given the different motivations of the two types of host countries, "Reliable" host countries have lower performance costs than "Unreliable" host countries. Considering the costs and benefits of "signing BIT" strategy, whether the host country adopts this strategy depends on whether the benefits brought by the strategy after the host country adopts it exceed its costs [19; 20; 21]. For two classes of the host country, if both take "signing BIT" strategy (in the case of incomplete information, not trusted host state imitate trusted host country strategy of motivation, the purpose is to attract investors to invest), then the "trusted" is a cost advantage of host country ("Reliable" host country "signing BIT" cost is lower than "Unreliable" host country).Therefore, if the cost of "Reliable" host country adopting " signing BIT" strategy is greater than its benefits, the "Reliable" host country will give up the strategy. Based on the rational assumption, the "Unreliable" host country will definitely give up the strategy (the reason is that the cost of "Unreliable" host country signing BIT is greater than that of "Reliable" host country).

For investors, on the premise that the expected return of investors is positive, if the host country signs BIT, it will form a positive investment incentive for investors. When the expected return of the investor is zero, the investor can be considered as a potential investor (the investor may or may not invest). In this case, whether the host country "signing BIT" is more sensitive to the influence of the investor in judging the type of the host country.

To sum up, the game between host country and investor is the signal transmission game of incomplete information. In the signal transmission game of BIT, the host country is the sender of the signal and the investor is the receiver of the signal. The specific game process is:

1) There is a "natural person" randomly assigned host country type with probability "θ", in which "Reliable" host country is assigned with probability "θ", and "Unreliable" host country is assigned with probability "$1-\theta$".

2) The host country chooses its own action strategy according to the allocation of "natural persons", that is, whether to adopt the strategy of "signing BIT". " Reliable" host countries attract investors by "signing BIT", or "not signing BIT", and have been protecting investors' interests in a cooperative way. At the stage when investors decide whether to invest, host countries adopt two strategies (The strategy of "signing BIT" or "not signing BIT" is adopted) to confuse investors with incomplete information, so as to attract their investment, and obtain investment benefits through non-cooperation after investors establish investment projects.

3) According to the action strategies of the observed host country and according to Bayes' rule, investors constantly make Bayesian correction for the posterior probability of the judgment of different types of host country and select their own action strategies accordingly. Investors have two strategies: First, investors adopt the "investment" strategy; Second, investors adopt a "don't invest" strategy.

Now take two stages as an example, where the host country takes the strategy first, the investor act again according to the strategy of the host country.

1) Collection of host country types.

Suppose there are two types of host countries, and the set of host countries is:

$H = \{h_1 = R$ (Reliable host country); $h_2 = U$ (Unreliable host country)$\}$.

2) Collection of actions of the host country.
The two types of host country "R" and "U" first send signals, and the signal set is:
G = {g_1 = Y (signed BIT); g_2 = N (no BIT signed)}.

The costs incurred by the two types of host countries in negotiating and signing BIT are recorded as "BC"; In view of the different motivations of the two types of host countries, after the entry into force of a bilateral investment treaty, the performance cost of host country R is lower than that of host country U. "BR" is recorded as the performance cost of host country R, "BU" is the performance cost of host country U, then there is "BR < BU", and further, there is "BC +BR < BC +BU".

3) Collection of actions of investor
Investor M act again according to the received signal G, and investor M's strategy set is:
A = {a_1 = I (Investment); a_2 = DI (Don′t investment)}.
The prior probability of investor M to "Reliable" host country R is: P (R) = θ (0 < θ < 1);
The prior probability of investor M to the "Unreliable" host country U is: P (U) = 1−θ;

Whether investors M based on the host country to send "signing BIT" signals, according to the Bayesian rule, to determine whether the host country as "Reliable" the probability of the host country, in order: "P (R | Y)", "P (R | N)", "P (U | Y)", "P (U | N)", and based on the modified Bayesian probability, to choose their own strategy.

4) Benefits of rational participants:

I. In the case that the action strategy of the host country H is "N" : if the strategy of the investor M in the host country R is "I", then the benefit of the investor is "YM" and the benefit of the host country R is "YH"; If the strategy of investor M in the host country U is "I", the benefit of investor is "EM" and the benefit of host country U is "EH". If investor M adopts strategy "DI", the returns of both host countries and investors are "0".

II. In the case that the action strategy of the host country H is "Y" : if the strategy of investor M in the host country R is "I", the benefit of the investor is "Y'M" and the benefit of the host country R is" Y′H−BC−BR "; If the strategy of investor M in the host country U is "I", the profit of investor is "E′M" and that of the host country U is " E′H−BC−BR "; If investor M adopts the strategy "DI", the investor's return is "0", and the return of the two types of host countries is "−BC".

III. For the host country H, if the strategy is "Y", because the expected return of investor M is positive, M will increase its investment, and then the return of H will also increase accordingly. Therefore, for the host country R there is "Y′H > YH > 0", for the host country U there is "E′H > EM > 0"; For investor M, if M invests in R, there is "Y′M > YM > 0"; but if M invests in U, there is "E′M < EM < 0" (EM < 0 means that the investor may suffer from the direct expropriation of the host country, or the indirect expropriation of the host country has a large enough erosion degree, and its effect is equivalent to the direct expropriation, resulting in the termination of the investment project. On the premise that the expected return of investors is positive, when M increases investment after receiving the signal of "signing BIT", "E′M < EM" will occur due to U's motivation of non-cooperation).

IV. Set the revenue function of host country R as: VR (gj , ak , R) , j = 1,2; k = 1,2;
The revenue function of the host country U is: VU (gj , ak , U) , j = 1,2; k = 1,2;
Returns for investors: VM (gj , ak , hi) , I = 1,2; j = 1,2; k = 1,2;
Under different strategies, the specific benefits of each party are shown in Table 1.
When the two host countries adopt strategy "Y" at the same time, then:

$$P_{(R|Y)} = P_{(R|N)} = P_{(R)} = \theta;$$

$$P_{(U|Y)} = P_{(U|N)} = P_{(U)} = 1 - \theta;$$

$$a^*_{(Y)} = \underset{a \in A}{\arg\max}\left[P_{(R)} \cdot V_M(Y, a, R) + P_{(U)} \cdot V_M(Y, a, U)\right] = a_1 \ ;$$

$$a^*_{(N)} = \underset{a \in A}{\arg\max}\left[P_{(R)} \cdot V_M(N, a, R) + P_{(U)} \cdot V_M(N, a, U)\right] = a_1.$$

Table 1: Benefits of all parties under different strategies

Revenue to reliable host country R	Revenue to unreliable host country U	Investor M returns
$V_R(g_1, a_1, R) = Y'_H - B_C - B_R$	$V_U(g_1, a_1, U) = E'_H - B_C - B_R$	$V_M(g_1, a_1, R) = Y'_M$ $V_M(g_1, a_1, U) = E'_M$
$V_R(g_1, a_2, R) = -B_C$	$V_U(g_1, a_2, U) = -B_C$	$V_M(g_1, a_2, R) = 0$ $V_M(g_1, a_2, U) = 0$
$V_R(g_2, a_1, R) = Y_H$	$V_U(g_2, a_1, U) = E_H$	$V_M(g_2, a_1, R) = Y_M$ $V_M(g_2, a_1, U) = E_M$
$V_R(g_2, a_2, R) = 0$	$V_U(g_2, a_2, U) = 0$	$V_M(g_2, a_2, R) = 0$ $V_M(g_2, a_2, U) = 0$

Source: calculated by authors.

If "Y′H−YH > BC +BR and E′H−EH > BC +BU" (this is the sufficient condition for the two types of host country to sign BIT: "BC +BR" is the cost of host country R after signing BIT, "Y′H−YH" is the increase of investor M after signing BIT of host country R, and the increase of income gained by host country R accordingly; Similarly, "BC +BU" is the cost generated after the host country U signs BIT, and "E′H−EH" is its corresponding increment of revenue), then:

$$V_R\left(Y, a^*_{(Y)}, R\right) > V_R\left(N, a^*_{(N)}, R\right);$$

$$V_U\left(Y, a^*_{(Y)}, U\right) > V_U\left(N, a^*_{(N)}, U\right).$$

At this point, a pooling equilibrium occurs, and the equilibrium strategy is: (Y, Y), (I, I).

Similarly, all kinds of equilibrium solutions under the signal transmission game can be found, as shown in Table 2.

Pooling equilibrium under the situation I: Two types of the host country after signing BIT yields were greater than the cost ("Y′H−YH > BC +BR", "E′H−EH > BC +BU"), so the two kinds of the host country will compete against each other to sign BIT, attract investors to invest in competition, two kinds of the host country of the strategy "Y" is adopted, at this time, investors can′t effectively distinguish types of host country, as investors expected return is positive ("θ · Y′M + (1−θ · E′M > 0"), investors will continue to invest, Increase the size of your investment in different types of host countries ("Y′M" for the return on investment in host country R and " E′M" for the return on investment in host country U).

Table 2: Signal model equilibrium solutions

The premise condition	Type	Equilibrium	Investor optimal strategy	Host country optimal strategy	Situation
$\theta \cdot Y'_M + (1-\theta) \cdot E'_M > 0$ $Y'_H - Y_H > B_C + B_R$ $E'_H - E_H > B_C + B_U$	Pooling equilibrium	(Y, Y) (I, I)	$a^*_{(Y)} = a_1$ $a^*_{(N)} = a_1$	$V_{h_l}(Y, a^*, h_l) > V_{h_l}(N, a^*, h_l)$	I
$\theta \cdot Y'_M + (1-\theta) \cdot E'_M > 0$ $Y'_H - Y_H < B_C + B_R$ $E'_H - E_H < B_C + B_U$	Pooling equilibrium	(N, N) (I, I)	$a^*_{(Y)} = a_1$ $a^*_{(N)} = a_1$	$V_{h_l}(N, a^*, h_l) > V_{h_l}(Y, a^*, h_l)$	II
$\theta \cdot Y'_M + (1-\theta) \cdot E'_M <$	Pooling equilibrium	(N, N) (DI, I)	$a^*_{(Y)} = a_2$	$V_{h_l}(N, a^*, h_l) > V_{h_l}(Y, a^*, h_l)$	III

0 $Y_H > 0$ $E_H > 0$			$a^*_{(N)} = a_1$		
$E_M < 0$ $Y'_H - B_C - B_R > Y_H > 0$ $E'_H - B_C - B_U < 0 < E_H$	Separating equilibrium	(Y, N) (I, DI)	$a^*_{(Y)} = a_1$ $a^*_{(N)} = a_2$	$V_R(Y, a^*, R) > V_R(N, a^*, R)$ $V_U(N, a^*, R) > V_U(Y, a^*, U)$	IV

Source: calculated by authors.

Pooling equilibrium under the situation I: Two types of the host country after signing BIT yields were greater than the cost ("Y′H−YH > BC +BR", "E′H−EH > BC +BU"), so the two kinds of the host country will compete against each other to sign BIT, attract investors to invest in competition, two kinds of the host country of the strategy "Y" is adopted, at this time, investors can′t effectively distinguish types of host country, as investors expected return is positive ("θ · Y′M + (1−θ · E′M > 0"), investors will continue to invest, Increase the size of your investment in different types of host countries ("Y′M" for the return on investment in host country R and " E′M" for the return on investment in host country U).

Pooling equilibrium under the situation II: the two types of host country sign BIT costs were greater than the benefits, so the two kinds of the host country of the strategy "N" is adopted, at this point, investors still can′t effectively distinguish host type, but given the expected earnings of the current investors are ("θ · Y′M + (1−θ) · E′M > 0"), so the investors to invest, but doesn′t increase the existing investment scale.

Pooling equilibrium under the situation III: the investor expects that after receiving the "signing BIT" signal from different types of host countries, the expected return to increase the investment scale in different types of host countries is negative ("θ · Y′M + (1−θ) · E′M < 0"), and the investor will not increase the investment scale again on the basis of the original expected investment. The host country also doesn′t send a "signing BIT" signal to avoid the cost of signing a BIT.

Separating equilibrium under the circumstances IV: when the host country R sign BIT cost ("BC + BR") is less than its gains after the sign BIT ("Y′H - YH"), and the host country after U sign BIT earnings are insufficient to cover the cost of the sign BIT (" E′H−BC−BU < 0"), "Signing BIT" is an effective signal for investors to distinguish "untrusted" host country from "trusted" host country.

Conclusions

Under the analysis framework of Sasse, the model assumptions were further relaxed, and the conditions for the bilateral investment agreement as an effective signal ("Y′H−BC−BR > YH","E′H−BC−BU < 0") were found based on the non-negative expected investment return of investors. In essence, due to the differences in BIT compliance costs, different types of host countries have different costs of sending BIT signals. Only host countries with superior investment environment will face smaller compliance costs, which provides investors with the basis to distinguish different types of host countries, thus alleviating the time inconsistency problem to a certain extent.

The signaling power of the BIT is limited. For investors, a positive expected investment return is a sufficient condition for them to adopt an investment strategy. Even with incomplete information, investors may face the risk of "Unreliable" host country "non-cooperation". Of course, BIT signaling can improve investors' expected returns to some extent, especially if BIT is used as a valid signal.

Signing up to a BIT costs money, especially when the high standard BIT is constantly being upgraded. If under the premise that the existing BIT, two types of the host country in confusion is balanced, investors cannot identify the two, the competition of attracting foreign capital in the relationship between the host country, encourages each other constantly upgrade BIT version and content, until the poor investment environment of host countries abide by the high cost to cannot cover the benefits brought by the signing BIT, this for the host country in the capital competition, need to bear the cost of a larger especially poor that one party to the environment. Under the premise that global investment rules are not yet unified, BIT is still the bearer of international investment rules. For host countries, BIT versions and contents should be signed selectively according to their own needs to introduce foreign capital, to balance the relationship between investment interests and domestic economic sovereignty.

Abstract

World processes associated with the transition to a new stage of economic development called the "new economy", "knowledge economy", are characterized by a high level of innovative activity, which is manifested in the introduction of new knowledge and innovative technologies. Regional economies in the context of cluster-network development and the emergence of digital technologies impose new requirements on people who must possess digital competencies and improve their knowledge continuously, throughout their lives. In this regard, the role of educational technologies offered on the market is increasing and making it possible to continuously study on a distance basis using e-learning opportunities. The article substantiates the thesis that innovations and knowledge affect the cluster-network development of regions and countries; for the constant replenishment and renewal of knowledge, the expediency of using e-learning opportunities throughout life is substantiated. The statistical data of the TOP-25 developed countries according to the level of the Global Innovative Index (GII) (2018) are presented, as well as some other indicators related to it, namely: knowledge absorption, the state of cluster development, and knowledge technology output.

Keywords: Innovation, Knowledge Management, Clusters, Cluster-Network Structures, Digitalization, E-Learning, Global Innovation Index.

Introduction

Today, almost all world economies are interested in moving to an innovative path of development. This is due to the increased demand for innovations - new knowledge and original technological solutions [1,21,29]. The objective needs to take into account the innovation factor is becoming a decisive condition for the further development of the modern economy. A long-term statement of the fact that economic growth in the region can be achieved only on an innovative basis with the active use of modern scientific and innovative developments, should move on to real action.

However, the arrival of new technologies is not supported by the creation of new, progressive paradigms in education. Technologies make it possible to access new information, but, on the other hand, exacerbate the problem of specialized and regional-sectoral imbalance in the training of highly qualified specialists. Moreover, this problem is aggravating at a very fast pace [26].

Knowledge management is not only database management, not administrative regulation, it is, first of all, the management of people who are united by a common regional economic problem, generate ideas, develop development models, and are able to effectively act towards the progressive implementation of changes [14,15,19]. The driver of development, the source of growth and prosperity, as well as the factor determining the competitiveness of enterprises, countries, and regions, is the creation, use, and effective exchange of knowledge. The knowledge

Suprunenko“ Knowledge and Innovation as Key Drivers of Craster-Network Development of The Regions and Countries in The Conditions of Digitalization” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

economy is a type of economic development in which the development of science and education, as well as other knowledge-intensive industries and services, is predominant.

An important condition for building an innovative economy is the modernization of the educational system. To ensure innovative growth, a transition to a “knowledge society” and a knowledge-based economy is necessary [18,26]. In addition, global competition is now intensifying, including the competition of education systems, which encourages continuous improvement of technologies, the introduction of innovations, and rapid adaptation to the dynamically changing conditions of our time [22]. In addition, there is another serious problem that is relevant for Russia as well - the inconsistency of the level of professional training of specialists with the social order and the requirements of employers [16]. Also, getting a quality education is included in the range of value orientations of citizens. All these, in some places not related to each other, problems caused by digital transformations [12], modern scientists have found the most optimal solution - the creation of educational clusters and cluster-network associations [13].

Method and Methodology

The main research method is the comparative method, which makes it possible to provide a reasoned substantiation of the author's thesis about the interrelation and mutual influence of knowledge and innovation on the clustered development of regions and countries.

Results

The functioning of the cluster-network model of the region depends on many factors: the creation of an intersectoral, intersectoral, and interdepartmental system of public administration and business structures; development of multichannel resource supply; creation of a unified information system; training of professional leaders with knowledge of strategic management, etc. According to N. Smorodinskaya, firstly, the drivers of economic growth of clusters are the effects of knowledge overflow or externalities that arise not only within industries (Marshall externalities inherent in traditional agglomerations) but also between related industries (Jacobian externalities, generating diversification of production), represented in clusters [30]. At the same time, the effects of the overflow of tacit knowledge (tacit knowledge) circulating within the partnership network, in particular between the cluster members (what Marshall called a "special atmosphere"), are of particular importance. Secondly, innovations require a systematic approach, that is, the presence of a system of network connections of agents for the joint creation and distribution of innovations [30].

The intellectualization of the economy through the creation, use, and distribution of new knowledge becomes the basis for the development of society, since “unlike traditional resources, information and knowledge are not depleted in the process of use and, included in the production system, have a much greater value than outside it” [8]. Under these conditions, clustering processes play a significant role [32], as evidenced by the data given in Table 1.

Many modern researchers agree that knowledge plays an important role in generating innovations, which, in turn, are the drivers of cluster-network development of regions and countries in general [4,5,9,10,25,31]. At the same time, knowledge management acquires not only regional but also national significance [22]. The data in Table 1 show that there is a certain (albeit indirect) relationship between the innovativeness of a region (country), and the development of clusters, although without conducting a special study that goes beyond the scope of this article, it is impossible to accurately establish the nature and closeness of this relationship.

As I. Nonaka and H. Takeuchi argue, when organizations innovate, they do more than simply process information from external sources to solve existing problems and adapt to a changing environment; organizations on their own create new knowledge and information necessary to develop a new approach to both problems and their solution, and as a result - to change the organizational environment [2] and, ultimately, create a favorable educational environment.

Table 1 - Indices of innovativeness and clustering (2018)

Country	Global Innovative Index (2018)		State of Cluster Development		Knowledge absorption		Knowledge Technology Output	
Switzerland	68.4	1	68.6	11	53.3	9	74.9	1

The educational environment as a system arises remains and develops where there is a need for the exchange of knowledge between its subjects. Under the influence of objectively forming environmental factors that require updating existing knowledge, an imbalance of the educational environment arises, which inevitably leads to an asymmetry of all its components, the formation of new goals, educational

content, methods, and forms of education, predicted results of educational activities and the resources available for this: human resources. , financial, scientific, informational, and others.

The result of the mismatch is the search for new educational technologies, resources, reserves of innovative development, which, in turn, lead to the discovery of new ways to radically change the educational environment. There is a public need for new knowledge, competencies, skills to act for all subjects of the educational environment [6], as well as the need for educational programs of lifelong education for adults ("lifelong learning") using e-learning [17,23].

An important component of the process of generation, use, reproduction, and distribution of new knowledge is knowledge transfer, the essence of which is the transfer between various organizational structures and knowledge processes, which are not only the initial data, but also the end result of the innovation process, where external knowledge is combined with internal ones. accumulated in the course of previous innovation processes, including technologies, experience, and skills, are transferred from one side to the other, leading to innovations in the economy and social sphere [24].

The above processes of creation, use, reproduction, and transfer of knowledge, aimed at increasing the level of socio-economic and innovative development of regions, can be defined as knowledge management. At the same time,

collective knowledge is based on individual knowledge, therefore, the knowledge management process should affect each person, because it is the person who is the main value, because thanks to his knowledge and interaction in the team he can provide the competitive advantages of any enterprise [27]. Thus, the management of innovative knowledge is the basis for the development of business entities, regions, and the country [22]. The new knowledge gained at the regional level is transformed into competencies, which are manifested in the creation of innovative products, processes, and technologies, thereby ensuring an increase in the competitiveness of these entities. In the context of the above, the cluster approach is viewed as a promising direction for the innovative development of the regional economy [3, 7, 11, 20].

Conclusion

Knowledge, as a resource, in the knowledge economy, is an endless source. The main bearer of knowledge is an educated person. Therefore, the information environment should provide a significant increase in the aggregate knowledge in society, the development of human capital. This predetermines the free exchange of knowledge and active consumption of knowledge, especially in the educational environment]. The knowledge economy is inextricably linked with a constant cycle of innovative development. The ability to create new knowledge, technologies, processes, the ability to access new knowledge, and the possibility of its effective commercial use are all fundamental elements of competitiveness, both at the regional and global levels. Innovation is the main form of translating knowledge into wealth and is a key characteristic of the knowledge economy. As studies by economists show, innovation today is the main source of economic growth and the most important factor in the competitiveness of enterprises, regions, and national economies. The development and implementation of innovations are closely linked with the creation, assimilation, and application of knowledge, that is, innovation and knowledge are a single whole, which cannot be divided in principle. The ability to perceive knowledge is, first of all, the ability and ability to learn, and, therefore, to assimilate and use the acquired knowledge in practice.

Abstract

The equestrian sector has an important role in protecting the environment, social welfare and economic growth. Currently this sector is in the development stage both internationally and nationally. The horse remains on a competitive market regardless of the form of tourism, management or marketing, because it respects the natural, social and economic integrity of the environment, ensuring the exploitation of natural and cultural resources for future generations. Sustainable tourism development is not just a concept when it comes to horses but it is a starting point for meeting the needs of the tourists and of the local population.

In Romania, equestrian sports are not as developed as in other states, whether they are sports events or recreational activities.

The aim of the study is to provide a broader perspective for the future management of the equestrian industry, as well as for the development capacity of this market.

Keywords: Equestrian sports, economy, tourism, management, sustainable development.

Introduction

The equestrian sector underwent a huge transformation mainly in the second half of the last century (Baldacchino et al., 2015). The role of horses in agriculture has been taken over by tractors and machinery, while animals have been increasingly kept for recreation and sports (Fine, 2010), the equestrian activities being among the few growing industries (Helgadóttir and Sigurðardóttir, 2008). Unlike the main heavily subsidized agricultural sectors, the current equestrian sector is market-driven with minimal government intervention.

To develop a harmonious society, the equestrian sport provides a favourable development environment for the sports industry, but also for the economy (Newsome et. al, 2008). Equestrian sport as an emerging industry has a critical impact on the Romanian economy, but it has still been facing opportunities and challenges (Plesoianu, 2017). So far, the tourism that can be developed due to equestrian sports has received minimal attention. In any case, it has been found that the segment offers significant opportunities especially for regions and rural communities that strive to expand and develop their tourism product (Lane, 2009).

Little research has been done on the small-scale event sport tourism (Ritchie, 2004), especially when organized in regional areas. Events based on equestrian sports encourage participants and spectators to stay at least one night away from their place of residence, so this has increasingly developed the leisure industry, as well as tourism (Kotze, 2006). These sport-based events, whatever there is a serious competition structured at international level or

Cite this Article as: Oana Daniela LUPOAE, Andrei-Mirel FLOREA, Riana Iren RADU, Dumitrache Bogdan BRATOVEANU and Silvius STANCIU "Economic and Social Influences of The Equestrian Sector Development in Romania" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

of a recreational and non-competitive kind, can make a positive contribution to the economic mix of cities and regions (Burgan and Mules, 2001) by improving sports facilities (French and Disher, 1997), by strengthening a target image (Brown et. Al., 2002) and by supporting demand management (Hingham and Hinch, 2002). The objectives of the present paper are represented by the analysis of the theoretical and empirical aspects of the importance of equine rearing, but also by the analysis of the economic and sustainable impact of the equines on society.

Methodology

In what concerns the research methods, the method most frequently used in the paper is the comparative method, and the arguments justifying the use of this method are that the similarities and dissimilarities between different countries regarding equestrian sports have been identified. The approach and the way of carrying out the work are impartial, able to answer punctually to the following questions:

Q1: Can the equestrian sector be an important part of a country's economy and ensure the development of tourism?
Q2: Can the equines play a sustainable role in sustainable development?

The information was collected by literature review as scientific databases (Clarivate Analytics, Elsevier, ResearchGate), international databases (FAOSTAT, EUROSTAT) and national statistics (National Institute of Statistics NIS). The results of research showed the importance of this system in the context of sustainable rural development through agro-tourism and equitation.

Results of the study

The economic and social impact on the equestrian sector

The turnover generated by the equine animal sector represents an important subject in research. The equines play an important role in the national economy and agriculture for many European countries. The stud farms are part of the traditional agricultural enterprises which have managed to develop in the last years both on social and economic levels. The social and economic activities focused on equines involve many sectors, as it is presented in Table no. 1.

Table 1: Impact of equine activities in various activity sectors

Activity	Impact		Explanations
	economic	social	
Services			
Equitation	✓	✓	Equitation is one of the healthiest sports. A group of researchers from Tokyo University of Agriculture conducted a study, proving that the children who participated to the equitation session showed improvements in cognitive skills, the horse-riding courses supporting and perfecting the memory, learning and problem solving (Ohtani et al., 2017).
Hippotherapy	✓	✓	The use of horse-based therapy leads mainly to neurological and sensorial improvements (Corraland and Fernández, 2011). Therefore, this discipline is especially indicated for certain physical and intellectual disabilities and for some psychological disorders, being quite effective in assisting paralyzed or autistic people (Cuypers et. Al, 2011). Hippotherapy is practiced by the Riding for the Disabled Association and by Donkey Sanctuary organization in the United Kingdom. One or many organizations or individual members of the Federation of Horses in Education and Therapy International AISBL (HETI) is/are registered in 21 EU Member States.
Sport contests	✓	✓	The largest turnover is found in the horse racing industry, the most popular being the jump racing, France being one of the countries with the highest number of races (Liljenstolpe, 2009; Craig, 1982)
Sports betting	✓	✓	The end of the 19th century was marked by the appearance of "pari-mutuel" bets. Modern bettors owe the emergence of this system to the Frenchman Pierre Oller. Currently, "pari-mutuel" betting is considered to be one of the most widespread betting systems on the market. People bet certain amounts of money on a certain result, and the money is placed in a prize pool. Once

Activity	Impact		Explanations
	economic	social	
			the result becomes known, the prize pool is divided between the winning bettors. Betting has always given this sport a certain charm, probably this is the reason why horse racing has managed to maintain its professional sports status over the years. After the First World War, the racetracks have begun to attract a larger audience eager to take a look at the great and incomparable horse Man o 'War. It has become a legend among bettors because no other horse has achieved such incredible results - 20 races won out of 21 starts and winnings of $ 249,465 (Drager, 2020) The betting turnover varies in different European countries, the highest betting turnover being in the United Kingdom, France, Ireland, Italy and Sweden. The race betting is an important source of income for the equestrian sector in France (Liljenstolpe, 2009).
Tourism	✓	✓	Unfortunately, the equestrian tourism is very poorly promoted in Romania, as compared to other countries, although the potential is much higher - a developed infrastructure, captivating routes, a tourist guide with training in the field and an attractive guesthouse can make it occupy an important position in the economy. Also, equestrian competitions can be organized in order to develop the equestrian tourism (Sigurðardóttir, 2018).
Energy capacity	✓	X	The Romanian horses have always been appreciated for their special qualities (energy capacity, tensile strength), managing in the past to contribute a lot to the development of agriculture.
Horse parades	✓	✓	An activity often encountered at various social and cultural events.
Products			
Equestrian trade	✓	X	Several criteria are taken into considering when establishing the price of a horse, out of which the most important is the "professional" skill of the animal. A race horse must have excellent speed, a regular and strong jump, the natural beauty of the movements being the result of an adequate training. The origin (pedigree) of the horses plays an important role. The zoo-technical principle "obtain the best from the best" has not been canceled, as champion parents often produce talented offspring (in any sport). The most expensive horse in the world costs $ 70 million, being the record holder-Fusaichi Pegasus (Mostfamouslist, 2019). The Frankel stallion has a national value of $ 200 million, but it is not for sale. Frankel is the winner of many prestigious races, the experts observing the uniqueness of the stallion, claiming that it has incredible power. The champion has ended its racing career and is famous for being the best producer of purebred horses in the world. 1974 was a landmark for tractors, because the first pedigree book of the Trakehner breed was created in that year (Trakenen horse breed is the national pride of Germany) (Exceltur, 2018).
Medicine	✓		Obtaining vaccines and serums
Human food	✓	X	o Horse meat The value of total horse meat imports was about $ 557 million in 2011, at a traded amount of 133.6 thousand tons. Global exports were about $ 568 million, at a quantity of 140.6 thousand tons of meat (Stanciu, 2015). According to the Observatory of Economic Complexity (OEC) in 2018, Italy was the largest consumer of horse meat, with a share of 24.7% of total imports worldwide. In Romania, as well as in the areas of Anglo-Saxon influence, the horse is not a traditional source of meat, but there is evidence of horse meat human consumption since ancient times. (Stanciu et all, 2013)
	✓	X	o Mare milk Mare milk is consumed fresh or as dairy products, the most known being CUMIS fermented dairy product ("water of life" in Kazakh) recommended in traditional medicine for various illnesses (tuberculosis, digestive diseases, tetanus etc.). Specialized herds are used for obtaining the kumis in some former Soviet Republics (the mares produce 15-20 l milk/day and 2000-3000 l milk /year).

Activity	Impact		Explanations
	economic	social	
	✓	X	○ Garments and leather goods The horse skin is used in garment, footwear and leather industry.
Artistic activities	✓	X	The protective hair (mane, tail) is used to make violin bows or brushes.
Obtaining fodder	✓	X	Blood, bones, hooves - production of protein meal, glues, special oils, gelatin (blood volume is 10-15% of the animal's weight)
Breeding Artificial reproduction (semen)	✓	X	Artificial insemination was quickly adopted as the main breeding technology in several countries. The development of artificial insemination has provided an opportunity in several farms in Europe, including Romania, this technology calling for greater transparency in different countries regarding the genetic quality of marketed stallions - in the world of horse breeders, "genetics is king". Big Star is one of the most valuable horses with the most spectacular shows of all time; one can pay $ 1,200 for a single sequin, and maybe in three or four years the resulting foal can be sold for few $ 100,000. One gallon (4 liters) of this horse's semen is worth $ 4.7 million. Once collected, the semen can be separated and sold in small tubes called sequins (BI, 2017).
Farmyard manure	✓	X	It is used in agriculture as fertilizer or in producing bio fuels.

Source: Issued by the authors

According to information provided by the International Equestrian Federation, the equine sector is worth over € 100 billion annually (Girling, 2017).

According National Economic Impact Study of the American Horse Council Foundation (2017), the horse industry contributes about $ 50 billion to the direct economic impact on the U.S. economy and has a direct impact on employment of 988,394 jobs (EBA, 2018). In addition, the industry itself contributes with $ 38 billion in direct wages, salaries and benefits. From these direct effects, the contribution of the horse industry spreads to other sectors of the economy. The addition of these corrugation effects results in an estimate of the horse industry's total contribution to the US economy of $ 122 billion and a total employment impact of 1.7 million jobs.

According to a study performed by Kusch (2013), the horse population in Germany is about 1.2 million means an increase in the last 40 years and the provision of a workforce for about 300,000 people, generating a turnover of over Euro 5 billion in 2012. Therefore, we will further analyse the link between the turnover generated by this sector, the number of employees in the field and the horse population in different countries, on the one hand, and the link between costs and revenues, on the other hand.

❖ *The turnover generated by the equestrian sector, the number of employees in the area and the horse population in various countries*

The Food and Agriculture Organization of the United Nations (FAOSTAT) estimated in 2018 that the number of horses in the world is 57,780,233, Romania, the United Kingdom (Great Britain) and Germany having the largest number of horses among the countries in the inveterate strong countries of the European Union (Nils-Gerrit Wunsch, 2020). Based on the data provided by Eurostat, a higher horse population density occurs in regions with a higher level of consumption, a higher level of education and low unemployment rates.

Figure no.1 showed the population of horses in regions that give a special importance to equestrian sports.

Figure 1: World horse population

Source: Authors, based on EBA data (2017)

As we can observe, the largest share in the number of horses is held by Europe and USA; accordingly, a comparative study on these two regions on horses and employees in this area will be performed (Figure no. 2).

Figure 2: Comparative statement between Europe and the USA

Source: Authors, based on EBA data (2017)

Approximately 4.6 million employees are directly involved in this sector in the USA, which has a direct economic impact of $ 50 billion. The USA has global herds assessed at 9.2 million horses, being above the level of Europe. According to the Report on the responsible ownership and care of equidae (INI, 2016/2017) prepared by the European Commission, the Directorate for Agriculture and Rural Development, the estimated population of equidae in Europe is 6-7 million, using for rearing over 2.6 million hectares of land, being generated a job for every 6-7 animals raised.

Figure 3: Status of income obtained from the equestrian sector.

Source: Authors, based on EBA data (2017)

The European equine sector is worth over € 100 billion a year, with an additional € 27.3 billion in 2013 due to the betting sector. The taxes related to this sector at European level amounted in 2016 to over Euro 1.1 billion (EP, 2017). According to the data presented in Figure no. 3, Europe occupies the first position at world level in the statistics of the income obtained after the exploitation of the equine rearing sector. France and the United Kingdom are very close what concerns the number of animals and of jobs created, being also the countries in Europe with the most developed sports competitions and horse sales. From a value point of view, the largest turnover of the sector is held by France.

In Europe, the horse population amounts to about 6-7 million, with the largest numbers in Romania, Germany and Great Britain, followed by France (Table no. 2).

Table 2: Status of equines per 1000 inhabitants and 1000 ha field- average 2017-2019

	Total number of equines				
Countries	**Number of equines**	**Population**	**Land area in ha**	**Horses /1000 people**	**Horses / 1000 ha**
Germany	442,000	82,437,995	35,738,600	5.4	12.4
Spain	307,441	43,886,000	50,599,000	7.0	6.1
Finland	74,400	5,266,000	33,844,000	14.1	2.2
France	370,881	62,998,773	64,380,100	5.9	5.8
Great Britain	418,856	60,393,044	24,249,500	6.9	17.3
Lithuania	16,324	2,289,000	6,530,000	7.1	2.5
Sweden	102,318	9,047,752	45,029,500	11.3	2.3
Romania	447,791	19,950,000	23,839,700	22.4	18.8

Source: Eurostat; the Romanian National Institute of Statistics (NIS), FAOstat

According to the National Institute of Statistics NIS, Romania held in the year 1961 a number of 1,000,000 of horses, number reduced almost to half at present (NIS, 2020).

According to studies in the UK and Sweden, the equestrian sector generates a direct turnover from € 1,100 to € 2,800 / year / horse (Häggblom et. Al., 2012; EBA, 2017). Considering an example in which 6-7 horses generate full-time employment, it can be estimated that the equine sector contributes between 15 and 20 million full-time jobs globally. This both vibrant and valuable industry contributes with £ 8 billion a year to the Great Britain economy. Direct employment in the equestrian sector in Great Britain amounts to 50,000 people, and employment due to the indirect effects of industry is estimated at 150,000-200,000, figures corresponding to 5-7 horses on a full-time job (BETA, 2019).

In a study issued in Pennsylvania, the results showed that each job in the equine industry indicates a return of 0.36 jobs in the rest of the economy and every dollar spent on horses creates production outputs and added value of $ 0.75 and $ 0.86 in the rest of the economy (Liljenstolpe, 2009). According to Alltech's Steve Elliot, the industry's annual economic impact is significant - involving about $ 300 billion and 1.6 million full-time jobs (EBA, 2017).

❖ *Income and costs for equine handling*

The equine rearing cost varies greatly depending on the Member State and the region concerned, the purpose for which the animal is used and how it is reared. However, given that it is difficult to find a new owner, especially to sell it to a contracted market, some owners choose to slaughter or euthanize the animals (where it is allowed by law and reasonable in price). Sadly, often those who take responsibility for rearing a horse do not know the costs involved or the time involved in handling this animal.

On the other hand, the equestrian consumption for Romanian per capita income is large, as only those with high economic power can develop such a sport - although through its noble temperament and unique charm the equestrian sport attracts more and more enthusiasts, it means an investment and large capital consumption.

The horse handling cost can range between 250 and 700 euro / month, according to the data presented in Table no. 3, the expenses depending on the food used, the number of employees, horse training, and the cost of training.

Table 3: Monthly cost for horse handling

Countries	Average value of a horse (euro)	Monthly cost of handling (euro)
Germany	-	500
Spain	7500	400-600
Finland	5000	400-750
France	7500	300-350
Great Britain	7000	500-700
Poland	5000	250
Sweden	7000	250-600
Austria	8-10000	250-400
Romania	6000	250-300

Source: Eurostat, (2020)

The total annual expenses from the equestrian sector are around € 2.6 billion in Germany, and total sales reach to € 5 billion. Moreover, 3-4 horses in Germany create a full-time job (Liljenstolpe, 2009). British horse racing alone generated direct, indirect and induced expenditure of £ 3.45 billion, and this industry contributed with a tax of £ 276 million in 2012.

The market for equestrian sports and equestrian activities in Europe is the most important in the world. 21% of the world's thoroughbred horses come from the European Union. 93% of the 2013 obstacle races took place in the European Union, in addition to another 21,000 gallop races and 43,000 trot races. Also, most of the events in 2014 organized under the auspices of the FEI (jumping, training, mixed and para-training competitions) took place in the EU.

In China, the state of the economy determines the equestrian industry to gradually attract more attention, as the development and progress of the equestrian industry has laid a solid economic foundation. For example, in recent years, the city of Wuhan - Hubei Province has become the only city that has researched and developed the preparation of racing sports and games, estimating a major propulsion of the economy. This has led to regional economic development through the national tax, solving part of the problem of the agriculture by improving animal husbandry, aquaculture, tourism and other related industrial chains, and the academic training in the field having a promoting effect. The number of horse clubs in China has increased by 1500% in recent years, from 90 in 2010 to 1400 in 2017 (EBA, 2017).

Accordingly, we can say that a careful, responsible and specialized management can lead the equestrian sector to a competitive economic binder and by organizing sports competitions, sports betting and equitation camps, we can develop equestrian tourism, and by obtaining valuable products (foals), the investment in this field could become profitable.

Can the equines have a durable role in sustainable development?

The equine rearing has also positive effects on the environment, not only on biodiversity and alternative land use, as a horse produces 20 kg of manure / day, which can contribute to a concentration of nutrients (especially nitrogen and phosphorus), and the droppings from horses in Europe reach almost 100,000 tons, the manure being used as fertilizer.

The disposal of manure generates significant amounts of organic material, depending on the management of the stands and the chosen bed material. The equines generate huge quantities of organic waste. Possible management situations and concepts vary depending on different regions, depending on manure applications such as fertilizer or disposal costs, availability and costs for bedding, stand management, economic viability of the energy generated.

The manure is a valuable resource for the application as an organic soil modification and for the generation of renewable energy. Due to the use of different bedding materials and different managements, the manure produced by horses varies greatly depending on the quantities and contents generated. Bioenergy production is still poorly adopted in Romania and should be encouraged through development programs.

The intensity of CO2 emissions of the current energy mix in Romania exceeds the average level of EU countries; this can be replaced by the supply of energy from renewable sources and low carbon dioxide emissions, economically and technologically viable.

Conclusions

Due to the diverting, healthy and noble characteristics of the equestrian sports, the number of private owners in Romania has grown continuously in recent years, so the demand for quality breeds and related products has begun to grow. An increasing number of enthusiasts are beginning to access the equine sector, especially in economically developed areas, which could favour the development of this sector.

Long term, the development perspective of the equestrian industry in Romania, based on a strategic and efficient management, has high potential. For stable economic development, the funds allocated to equestrian sports should be increased through political support, and through the passion of the public for horse racing and the cultivation of more professionals, a new point of economic growth can be formed.

This theme is a topical issue, in full development, being a field of research less exploited and debated in the literature at national level, but with significant importance for society. The problems faced by the Romanian economy start from the existing inconsistencies in the legislative framework and in the regional and global development strategies.

The horses represent the cultural heritage, social connections, economic stake, environmental issues and traditional rural development actors in the history of the Romanian people. Recently, complex researches (with zoo technical, socio-economic and environmental impact) on the equine rearing sector have started, but it is necessary to increase the number of information and statistical data at national level.

The research can be also developed at a multidisciplinary level for a complete analysis of the complex opportunities offered by the equine sector at European and global level.

Market Efficiency of Alternative Investments

Karol WOJTOWICZ

University of Warmia and Mazury in Olsztyn, Poland
karolw@uwm.edu.pl

Abstract

Market efficiency theory, introduced by E.Fama, is not only the most popular but also the most discussed theory of modern finance. According to the theory, security prices immediately and fully reflect all relevant information. The empirical research has focused primarily on financial instruments and stock exchange indices. Investors, striving to reduce risk by diversifying their portfolio, increasingly use alternative investment including commodity market instruments. From the beginning of the XXIst century, there is a relevant increase in commodity derivatives. According to the Futures Industry Association, the number of futures and options traded worldwide in 2018 amounted to over 30 billion contracts.

The main aim of the article is to verify the weak form of efficiency based on the selected alternative investment. The subject of the study was the most popular commodity derivates – crude oil, gold, copper, silver, corn, cocoa, and cotton. The analysis was carried out in the years 2000-2019.

Research has shown that alternative investments involving financial commodity instruments met the conditions of the weak form of market efficiency. Both the runs tests and auto-correlation tests proved random price formation. There were also no seasonal anomalies.

Keywords: market efficiency, alternative investments, commodities

Introduction

The increase in investment risk as well as the relatively low profitability of classic financial instruments encourage investors to look for new assets to build an optimal portfolio. The most popular alternative investments include real estate, hedge funds, private equity as well as products classified as emotional investments – art, alcohol (mainly wine, whiskey), noble elements, collectors' items. Investments in the commodity futures market are also an important group. The growing popularity of financial instruments based on commodities prices is related primarily to risk diversification. According to the Futures Industry Association, in 2018 over 30 billion futures and options were traded on the global financial markets. The growing number of investors, the way the market is organized, and the homogeneity of instruments are factors contributing to the efficiency of this asset. The main aim of the article is to verify the weak form of efficiency based on selected commodities market derivates. I included the most popular products - crude oil, gold, copper, silver, corn, cocoa, and cotton. The analysis was carried out in the years 2000-2019.

Literature Review - Information Efficiency

Efficiency is one of the most important terms in economics. As indicated by Dimson and Mussavian (2000), economists use the word in relation to operational efficiency, emphasizing the way resources are used to improve the functioning of the market. According to Samuelson and Nordhaus (2012), efficiency means the most optimal organization of production processes with given resources and technologies. It is a complex and multidimensional concept. As emphasized by Skrzypek (2012), efficiency can be defined using many terms, including efficiency, profitability, efficiency, productivity, effectiveness, purposefulness, rationality, as well as usefulness.

From a financial market perspective, the term efficiency is used to describe the market where the relevant information is reflected in the prices of financial assets. The scope and time in which the data will be included in the valuation of financial instruments determine the level of efficiency. The verification of the price formation process has been the subject of research for many years, but the genesis of information efficiency is seen in the paper of L. Bachelier – Theorie de la Speculation (1900). He pointed out that both past and present events are expressed in market prices, but often show no obvious relationship to their changes. The development of the contemporary

concept of information efficiency took place in the mid-twentieth century when quantitative methods began to play an increasingly important role in the science of finance[1]. In 1965, Fama presented that in a perfect capital market, prices provide precise signals regarding capital allocation. In the article, Fama (1970) defined aperfect market as a one where companies can make investment and production decisions, and investors can choose securities that are owned by the companies, assuming that the prices of the securities at any time "fully reflect" all available information. Also, Malkiel (1992) emphasizes in his definition that in the efficient market, significant information is fully and correctly taken into account in the process of financial instruments' price formation. Janicka (2008) drew attention that, the definition of market efficiency has been modified, even its author, E. Fama, has clarified the meaning of the term over the years.

Fama (1991) distinguished three forms of market efficiency – weak, medium (or semi-strong), and strong – depending on the scope of information included in the prices of the securities. The weak form assumes that the market prices contain all relevant information from the past, while the semi-strong form increases the scope of information with all current data. According to the third, a most controversial form of efficiency, the prices of financial instruments also include non-public data, available only to some investors.

Shleifer (2000) mentioned that one of the basic assumptions of market efficiency is the rationality of their participants. Investors making rational choices correctly evaluate assets. Even that irrational investors are observed in the market, their decisions will not be reflected in prices, as they will eliminate each other at an aggregate level. For that matter, possible systematic irrational behavior will be eliminated by arbitrage and thus will not affect the prices of financial instruments.

The most important consequence of the market efficiency hypothesis is the inability to systematically achieve above-average profits. New information is immediately taken into account in investor decisions and thus in the price of the securities. Therefore, neither the technical analysis, which forecasts stock prices based on historical data nor the fundamental analysis based on the current information contained in the financial statements, make it possible to identify undervalued stocks, allowing for higher-than-average returns. The efficient market means that financial assets are always correctly valued by investors, adequately to the set of available data. At the same time, the most advantageous investment strategy seems to be a passive strategy, which allows you to achieve a market rate of return with minimal transaction costs. Haugen (1996) noted that a highly efficient market means that financial instruments are priced on the basis of all the information, so each stock has a return that is consistent with its own risk and CAPM model. The relationship between the rate of return and risk is fully transparent concerning all available information.

Research verifying the process of financial assets valuation initially concerned mainly the stock markets and stock exchange indices. Along with the growing interest in commodity markets, papers devoted to this segment began to appear. However, it should be emphasized, that they focused primarily on the oil market, selected popular agricultural products, and indices of commodity markets. One of the first article devoted to information efficiency of commodities was published by Roll (1972), who verified the commodity price index. The author showed that the market is ineffective due to a significant level of correlation of rates of return. Market efficiency studies of selected commodities were also conducted by Bigman et al. (1983), Gjolberg (1985), Kaminsky and Kumar (1989), Panas (1991) Charles and Darné (2009), Paschke and Prokopczuk (2012), Kristoufek and Vosvrda (2014). In Polish literature, it is worth mentioning K. Borowski's publications on calendar anomalies on the market of commodity contracts and commodities indices. The results of research on the agro market and soft commodities were presented by K. Borowski and M. Łukasik (2015), as well as A. Górska and M. Krawiec (2017).

The Commodities Market Derivates As Alternative Investments

Alternative investments are systematically growing in popularity among investors. As emphasized by Borowski (2012) the most important factors influencing the dynamic development of this segment of finance include the increased diversification of investment portfolios (as a result of the 2007 subprime crisis), as well as investment profitability, especially in the period of the market downturn. It is difficult to provide an unambiguous definition of alternative investments, due to the wide range of instruments that can be included in this category. Aspadarec (2013) draws attention to the division into four categories of funds, popular in the world literature: hedge funds, commodity funds, private equity/venture capital, and real estate funds. Another classification is proposed by Kasprzak-Czelej (2013), who distinguishes three groups of alternative investments:

[1] The turning point was the introduction portfolio theory by H. Markowitz (1952) and its development by: Sharpe, Lintner, Mossin, Ross, Fisher, Jensen, Black, Scholes and others.

- classic alternative investments (e.g. real estate, ETFs, PE / VC funds),
- modern financial instruments (e.g. hedge funds, derivatives, structured products)
- emotional investments involving collector's items (e.g. art, noble elements, collector's coins, stamps, wines, whiskey, cognacs, and even autographs of famous personalities, old books and comics, vinyl records, and many others).

One of the most important areas of alternative investments is financial instruments based on commodities. According to Portykus (2016) portfolios containing commodities allow investors not only to diversify the risk but also to limit the negative effects of inflation (monetary and also resulting from the low supply). Sierakowska (2015) underline in her book that the specificity of the commodity market is related to the fact that it connects two worlds – it can be considered both from the point of view of spot transactions and from the perspective of the financial market of goods. The first area concerns direct transactions in certain raw materials and goods. The second "world" consists mainly of commodity exchanges dealing with trading in financial instruments based on the commodities prices.

The first organized market for commodity futures trading was the Chicago Board of Trade, founded in 1848. Other commodity exchanges appeared in the second half of the 19th century. In the past, commodity markets were perceived as completely or partially independent of financial markets due to the low degree of correlation of instrument prices [Gorton, Rouwenhorst, 2006].

Financial commodities instruments appeared in the seventies of the XX century. The growing popularity of commodity derivatives was so great that three decades later, turnover exceeded traditional commodity contracts. The interest in financial instruments based on commodities was also observed in developing countries - since 2003 the volume growth rate was more than twice as high as compared to more developed OECD countries[2].

Fig. 1: Commodity markets indices (2000 – 2019)

Source: own study, based on Thomson Reuters Eikon

Figure 1 presents three most popular commodity market indices against the main Warsaw Stock Exchange (WIG) index of the: (a) CRB index – the oldest global index of commodity prices in the world; (b) S&P GSCI (Goldman Sachs Commodity Index) – one of the most recognizable benchmarks for investments in commodity markets and (c) Bloomberg Commodity Index – formerly Dow Jones-AIG Commodity Index (DJ-AIGCI), introduced in 1998 based on energy, seeds, industrial materials, metals, "soft" commodities, and meat. Since 2000, the dynamic growth of all indices has been observed, ending with a temporary slump related to the global financial crisis. After 2008, the trend is reversed and the interest of investors in the commodity futures market has increased again. The growing share in raw material derivative portfolios, the purpose of which was to diversify risk, contributed to an increase in

[2] Data based on United Nations Conference on Trade and Development - Overview of the world's commodity exchanges.

commodity spot prices. The growing share in commodities derivative portfolios, aiming to diversify risk, contributed to an increase in commodity spot prices. As Tomaszewski (2016) points out, this phenomenon, called financialization, means a significant increase in the importance of the financial sector (institutions, investors) on the functioning of commodity markets, primarily the impact on the prices of goods and raw materials. On the other hand, the inflow of capital to the commodities market, and increased investor activity, causes an increasing correlation of price volatility in the commodity and equity markets, thus reducing the effectiveness of strategies related to minimizing investment risk. Daskalaki and Skiadopoulos (2011) showed that in the vast majority of cases the optimal portfolios were built of traditional asset classes, and the inclusion of commodities instruments reduced the benefits of diversification.

The significant importance of the commodities market in the global economy, the connection with financial markets, the increase in the share of financial investors contribute to a greater interest in mechanisms and regularities related to the functioning of this market segment. The process of valuation of commodities and raw materials, and consequently derivatives based on these assets, is a particularly important issue for both market participants and regulators.

Research Methodology & Results

Information efficiency in a weak form means that all historical data is included in the prices of financial assets. The implication of poor market efficiency is the inability to gain above-average profits using analysis based on historical prices.

Research verifying the weak form of market efficiency is based on the assumption of random walk of securities prices. In line with the information-efficient market hypothesis, stock prices should react randomly to the emerging data. As indicated, among others Malkiel (1998), changes in share prices are aleatory, and their movement follow the random walk process. By proving that there are no significant dependencies between the asset price (rates of return), it indirectly confirms a weak form of information efficiency. The tests also include the identification of market anomalies like calendar effects. Jajuga (2000) underline that according to weak form assumptions, price (rates of return) formation should not depend on time. Thus, the return on assets cannot be determined by a specific day of the week, week of the month, or month of the year, etc.

The weak-form efficiency study was based on selected commodity futures instruments. The research included the most popular commodities from various groups: crude oil, gold, copper, silver, corn, cocoa, and cotton. Daily and monthly (logarithmic) rates of return were used, calculated on the basis of closing prices in the period from 2000 to 2019.

The following methods were used to test the weak-form efficiency:

- series tests,
- autocorrelation tests,
- analysis of daily rates of return,
- analysis of monthly returns.

In the methodology proposed by Fama (1965) the runs tests enable the identification of possible relationships between the directions of successive price changes of financial instruments, based on the observation of specific sequences or the reverse of the directions of price movements of securities. In the study, the actual number of runs was determined and then compared with the expected runs number calculated according to the following formula:

$$E(s) = \frac{N \times (N+1) - \sum_{i=1}^{3} n_i^2}{N},$$

where:
E(s) – expected runs number,
N – total number of price changes,
n_i – number of price changes of each sign.

The study identified three directions of price changes: increase, decrease, and no change, while the run is price changes in the same direction. It was assumed that deviations of the expected runs number and actual runs number less than 10% prove that there is no significant relationship between price changes. A detailed summary of the results is presented in Table 1.

Table 1: Actual and expected series number

Commodities	*s*	*E(s)*	*dev(%)*
Oil	2582	2439,75	-5,83%
Gold	2587	2450,23	-5,58%
Copper	2616	2461,20	-6,29%
Silver	2563	2471,81	-3,69%
Corn	2542	2523,28	-0,74%
Cocoa	2518	2444,79	-2,99%
Cotton	2475	2416,07	-2,44%

In the years 2000 – 2019, the analyzed assets recorded approx. 2.5 thousand runs, with the recorded values slightly higher than expected. The deviations were at a low, negative level, ranging from -0.74% to -6.26%. In each case, the obtained results were within the error margin and did not exceed the 10% deviation. The results of the runs tests indicate that the pricing process (rates of return) of the analyzed alternative investments was consistent with the random walk process.

The second method of verifying the weak-form market efficiency was the autocorrelation tests, which allow for the identification of possible relationships between the volatility of asset prices in subsequent periods. To determine the autocorrelation coefficients, the following regression equation was used:

$$r_t = A + \beta \cdot r_{t-n} + e_t ,$$

where:

r_t – a rate of return in period t,
r_{t-n} – a rate of return in period t-n,
A – an intercept, which is the expected rate of return not related to the rate of return in the period n,
β – correlation coefficient (reaction strength) between rates of return over the period t-n,
e_t – random component.

For the statistical significance of the results, the t-Student's test was used, in which the zero hypothesis means no relationship between the rates of return H0: = 0, while the alternative hypothesis H1: ≠ 0 means the existence of a relationship between the rates of return.

$$t = \frac{\beta}{\sqrt{1-\beta^2}} \sqrt{n-2},$$

where:

t – test of significance,
β – correlation coefficient (reaction strength),
n – number of observations.

To identify the possible relationships between the rates of return in subsequent periods, the β coefficients of the analyzed instruments were calculated. When the value of the coefficient is significantly different from zero, it can be presumed that there is a relationship between the evolution of prices (rates of return). It may suggest a lack of randomness in the price formation process. The study verified the relationship between daily rates of return and rates of return realized with a delay of 1 to 5 sessions (t-1, t-2, t-3, t-4, t-5). The test results are presented in the table below.

Table 2: Rates of return correlation in subsequent sub-periods

Commodities	*t-1*	*t-2*	*t-3*	*t-4*	*t-5*
Oil	**-0,06363**	0,008106	0,024402	0,01141	-0,02763
Gold	-0,0073	-0,0068	-0,00622	0,016351	0,009836
Copper	**-0,0732**	0,007375	0,000283	0,013616	-0,02097
Silver	-0,00268	0,010319	0,003865	-0,00974	0,014901
Corn	0,015463	-0,00058	0,010133	0,000385	-0,01928
Cocoa	0,00304	-0,00824	**0,029462**	-0,01537	0,007261
Cotton	0,024421	-0,01178	-0,00373	**0,028836**	-0,00509

As with the runs tests, the test results show random price volatility. For most of the commodities, β coefficients did not show statistically significant relationships. The analysis of the autocorrelation of gold, silver, and corn confirms the absence of any correlation in the pricing process. On the other hand, a rare, slight correlation was observed in the case of oil and gold for the one-session delay, and also for cocoa for the third session and cotton – for the fourth session. No significant correlation was found for the remaining delays. The test results suggest that there is no correlation between the prices of commodities derivates. Although statistically significant coefficients were recorded, these are individual cases, and the majority of observations in the analyzed period indicated a random nature of the rates of return.

Another research method used is the analysis of the distribution of rates of return over time. The assumption of the rationality of market participants determines the inability to achieve above-average profits based on investment strategies implemented at a specific moment or time interval. The rates of return of the analyzed commodities were tested in two-time intervals – the distribution of daily rates of return and the distribution of monthly rates of return. To determine the distribution of monthly and daily rates of return, logarithmic measures were used following the formula below:

$$r = \ln\left(\frac{P_n}{P_{n-1}}\right),$$

where:

r – a logarithmic rate of return for the period from n-1 to n,
P_n – price in the period n,
P_{n-1} – price in the period n-1.

Table 3: Daily rates of return

Commodities	*Monday*	*Tuesday*	*Wednesday*	*Thursday*	*Friday*
Oil	-0,2370%	-0,0159%	0,0721%	0,1399%	0,1110%
Gold	-0,0056%	-0,0126%	0,0216%	-0,0035%	0,1398%
Copper	0,0176%	-0,0329%	0,0065%	-0,0229%	0,1340%
Silver	-0,0411%	0,0089%	0,0758%	-0,0841%	0,1324%
Corn	-0,0206%	-0,0100%	0,0742%	-0,0127%	0,0223%
Cocoa	-0,1407%	0,1299%	0,1187%	0,1073%	-0,1319%
Cotton	-0,0476%	-0,0406%	0,1170%	-0,0233%	0,0146%
mean	-0,0679%	0,0038%	0,0694%	0,0144%	0,0603%
standard deviation	0,0899%	0,0579%	0,0428%	0,0795%	0,1000%

As can be seen in Table 3, the rates of return on individual days of the week did not show systematic deviations that could be described as an anomaly. Relatively low returns can be observed in the case of investments made on Monday – almost all commodities (except for copper) achieved negative results. On the other hand, positive returns were recorded on Wednesday and Friday. However, it should be emphasized, that the level of profitability was so small that it did not allow to gain extra (above average market) profits. The dispersion also indicates the lack of systematic regularity in the distribution of returns of the analyzed investments.

Table 4: Monthly rates of return

Commodities	*Oil*	*Gold*	*Copper*	*Silver*	*Corn*	*Cocoa*	*Cotton*	*mean*	*standard deviation*
January	1,033%	2,730%	1,354%	3,405%	0,589%	3,227%	1,265%	1,943%	1,06%
February	4,804%	1,284%	2,331%	2,895%	4,365%	2,195%	1,915%	2,827%	1,20%
March	1,065%	-0,704%	1,420%	0,432%	-0,963%	-1,029%	0,233%	0,065%	0,91%
April	3,356%	0,536%	1,716%	-0,306%	1,335%	1,222%	-1,366%	0,928%	1,40%
May	1,521%	-0,038%	-0,545%	-0,966%	-0,841%	-2,520%	-1,886%	-0,754%	1,21%
June	1,496%	-0,494%	-0,245%	-2,787%	-2,560%	2,945%	-1,786%	-0,490%	1,97%
July	-0,685%	0,518%	2,253%	2,080%	-2,277%	-0,140%	0,133%	0,269%	1,46%
August	2,260%	1,838%	-0,970%	0,382%	0,737%	1,080%	-0,117%	0,744%	1,03%
September	-1,890%	0,822%	-0,572%	-0,772%	-3,693%	-0,362%	-2,012%	-1,211%	1,35%
October	-3,033%	-0,850%	-1,601%	-0,684%	2,689%	-3,274%	0,545%	-0,887%	1,92%
November	-3,323%	1,578%	1,029%	1,394%	1,789%	1,227%	1,192%	0,698%	1,66%
December	-2,585%	0,608%	-0,303%	0,439%	2,021%	1,009%	3,742%	0,705%	1,81%

The results of the research on the seasonality of monthly rates of return are presented in Table 4. The highest level of profitability was observed in February – the average profitability was over 2.8%. This month, a record high – over 4% rate of return was surveyed for oil and corn. However, it should be noted, that the „February effect" was characterized by a relatively high level of variability (standard deviation was 1.2%). On the other hand, in September the lowest rates of return were recorded (the average was at the level of -1.2%), although, as in February, they were not systematic – the standard deviation was 1.35%. It is worth noting that the pricing of commodities market instruments in individual months of the year differs from the trends observed in the stock markets. Popular seasonal anomalies such as the „January effect" or above-average rates of return in April (Great Britain) and July (Australia) did not occur in the analyzed investments. Positive rates of return in February and negative rates of return in September were both, relatively low, and at the same time with an increased level of dispersion. Applying the observed price regularities in practice did not provide investors with the opportunity to generate systematic above-average profits. Thus, the obtained research results do not provide evidence questioning the information efficiency in a weak form.

Conclusions

The market efficiency hypothesis is one of the most important theories of finance, it allows you to better understand the rules and mechanisms that follow financial markets. The scale and scope of changes in financial markets – including globalization, technological innovations, as well as the growing number of instruments increase the complexity of financial processes [Jajuga, 2010]. The aim of the study was to evaluate the market efficiency in a weak form on the example of selected commodities.

The research results show that the analyzed assets met the conditions of the weak form of market efficiency. The runs tests and rates of return autocorrelation tests prove that the commodity pricing process was random. What is more, there were no systematic regularities in the financial instrument price distribution. The prices of commodities did not show any significant seasonal anomalies, both daily and monthly. This means that investors did not have the opportunity to make additional returns from their investment on specific days of the week or in a specific month.

The results of the research allow the conclusion that alternative investments, which were selected commodity derivates, met the assumptions of the weak form of market efficiency. In future research on the information efficiency of the commodities market, it is worth considering instruments with lower liquidity. The scope of future research should also include an analysis of pre and post SARS-CoV-2 conditions on commodities market efficiency.

Divestments In Enterprises on The Example of Listed Companies In Poland

Konrad SZYDLOWSKI

University of Warmia and Mazury in Olsztyn, Olsztyn, Poland
szydlowski.k@uwm.edu.pl

Abstract

The article presents the problem of divestment in enterprises. The purpose of the research was to determine the scale and character of the divestment operations undertaken by companies in Poland. The subjects of the research were companies listed on the Warsaw Stock Exchange as part of the WIG-clothing sector index.

The results of the research indicated the limited activity of enterprises in the field of divestment. The subject of the divestment were mainly tangible fixed assets. To a much lesser extent, this process included intangible assets and long-term investments. The economic growth and good financial performance of the majority of analysed companies were important for making divestment decision. Companies were more willing to undertake investment projects than to limit their assets. The leading form of the divestment was the sale of assets, that enabled enterprises to obtain an additional source of financing.

Keywords: Divestment, Corporate Assets Management.

Introduction

Asset management is one of the key areas of enterprise activity. This issue referes to both – current assets that are directly related to operating activities, as well as fixed assets created through investments.

In the literature, a lot of attention is paid to issues related to the investment activities of enterprises. Each research problems concern the issues of capital needs, sources of financing, risk and profitability of investments, as well as investment timing. Investment activity is treated as a form of optimization of the value and structure of assets that are necessary to achieve the economic goals of the enterprise.

Optimizing the value and structure of assets is an extremely complex process. It is not only the issue of investment in new assets, but also divestment activities. The main goal of this process is to reduce assets resources and adapt them to current and future specifics and scale of operations.

There are many factors that prompt managers to take this kind of action. These include changing the profile or location of the business, adapting the company's activities to changing legal regulations, too high costs of assets maintaining, improving the company's image before the planned merger or acquisition. A fairly common impulse is the poor economic and financial condition of the enterprise and the need for restructuring measures. Besides, there are some macroeconomic determinants, such as GDP growth rate, dynamics of sales of goods and services, inflation and other factors. The problem is also related to the condition of the sector or industry in which the company operates.

The Nature, Determinants And Significance of Divestment In Business Operations

Considering the problem of divestment first requires defining this area of business activity. In the literature, the terms "divestment" or “deinvestment” are used interchangeably, but this is not always approved by individual experts. As indicated by G. Osberg-Pociecha, divestment is the activity of reducing or ceasing the current scale of the company's operations. It may be optional or forced, and the effect is to limit the resources held by their withdrawal, liquidation or sale (Osbert-Pociecha, 1998). A similar point of view is presented by Wojewodzic (2010), who identifies divestment with limiting the scale and scope of the company's operations or reducing its resources, which results in the improvement of the company's financial performance. On the other hand, Sobolewski and Wojtkowiak (2014) relate divestment to the scope of the company's activity. This is a broader concept that includes divestment measures,

Cite this Article as: Konrad SZYDLOWSKI “ Konrad SZYDLOWSKI” Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

consisting of limiting fixed assets, long-term investments, intangible and financial assets. In turn, according to Różański (2002), divestments are the opposite of the company's investment activities. The primary goal of both of these operations is to maximize value for shareholders.
Divestment may relate to various areas of the company's operation, including production, research and development and marketing. However, regardless of the area to which they relate, divestment goals are mainly to improve the financial condition of the enterprise in a broad sense, as well as to raise funds necessary to implement development projects.

There are many reasons why companies undertake divestment operations. They result from both – internal conditions of the company's operations, as well as external factors over which the company has no influence or this influence is significantly limited. Mishra (2016), as one of the main reasons for divestment, indicates the negative impact of sold assets on other areas of the company's operations. The Author also indicates such aspects as the need to pay off debt, increase working capital, lack of human resources potential, as well as negative market trends.

Accorging to Szydłowski (2018) the reasons for the divestment are also the possibility of selling assets at an attractive price, limiting the scope or changing the location of the business and the need to change the production profile. Also, these are too high costs of maintaining particular assets, striving to change contracts with contractors, employees and managers, as well as improving the attractiveness of the company in the perspective of planned acquisitions, mergers or sales of the firm.

The financial condition of enterprises is also one of the key factors. It refers in particular to companies whose financial condition is deteriorating. It is reflected, i.a, in problems with financial liquidity, excessive debt, low profitability or generating losses. From this perspective, divestment is treated as a tool for restructuring a company threatened with bankruptcy. The capital obtained from divestments enables the reduction of debt, accumulation of financial liquidity, as well as investments enabling the company's development. Some methods of divestment are indicated, including sell-off, spin-off, spin-out or buy-out transactions. According to Moschieri and Mair (2005) the sale of useless (often unprofitable) assets or the separation of organized parts of the company, makes it possible to improve the financial situation and further development of the enterprise. As indocated by Djordjević and Djukić (2008) these kinds of activities also relate to the problem of downsizing, understood as a set of operations aimed at improving the competitiveness and economic performance of the company.

Divestments are also undertaken by enterprises in good financial condition. These group of companies undertake investment activities which result in the assets reproduction. The effect of these actions is the liquidation of worn-out machines, devices, production lines and other assets.

Another group of factors are macroeconomic conditions such as GDP growth rate, unemployment rate, inflation and interest rates. Poor economic conditions force enterprises to reduce the current scale of activity or business re-profiling. Disposal of assets is a result of such activities. On the other hand, good economic conditions make it possible to undertake reproductive investments which result in the sale of used assets.

Useful information on the reasons for divestment is provided by a report published by the consulting company Ernst & Young, entitled „Global Corporate Divestment Study 2019" (2019). The research presented in the document shows that the main motive prompting the managerial staff to undertake divestment was the low competitiveness of the company on the market and the need to improve the current business model. Among other factors, the need to raise funds for investments in new technologies, a convergence of the sector in which the company operates, as well as geopolitical uncertainty and macroeconomic situation were pointed out.

The above considerations show that divestments are very important for the proper functioning and development of the enterprise. The possibility of effective restructuring and recovering from the crisis, optimization of assets, adaptation of the business to changing market conditions, are only some reasons for undertaking such operations. According to Dębski (2005) an additional aspect that is worth paying attention to, is the fact that these activities are an alternative source of financing. The funds obtained in this way are included in internal financing instruments. They can be used for both - operational and investment activities, but due to their irregular nature, they should not be a leading form of raising capital.

Research problems and data

The purpose of the research was to determine the scale and character of the divestment operations undertaken by companies in Poland.

Nine companies listed on the Warsaw Stock Exchange were analyzed as part of the WIG-clothing sector index. The subject of the analyzes was the value and structure of assets divested, as well as the financial performance of companies, taking into account financial liquidity, indebtedness and profitability. The analysis also concerned the economic situation in Poland as well as the condition and prospects for the development of the clothing sector. The analysis was made from 2012 to 2018.

The source of data were annual reports of the analyzed companies, Statistics Poland, as well as a report prepared by PKO Bank Polski – one of the largest banks in Poland.

Empirical results

One of the key factors determining the extent of divestments is the current and forecast economic condition. Each figure is presented in Table 1.

Table 1: The economic condition of Poland in 2012-2018

Category	Year						
	2012	2013	2014	2015	2016	2017	2018
GDP growth rate	101.3	101.1	103.3	103.8	103.1	104.9	105.1
Dynamics of retail sales of consumer goods	103.4	102.7	104.7	106.2	107.0	107.1	X
Gross investment in fixed assets (mld PLN)	322.5	311.7	339.4	361.5	335.0	352.3	384.7
Unemployment rate (%)	13.4	13.4	11.5	9.7	8.2	6.6	5.8
Price index of goods and services	103.7	100.9	100.0	99.1	99.4	102.0	101.6
Profitability of corporate sector	3.6	3.7	3.7	3.2	4.1	4.4	3.7

Source: the Author, based on Statistics Poland.

In the analyzed period, various trends in the economic situation of Poland were noted. Until 2013, the economic downturn took place, which was reflected in the weakening dynamics of gross domestic product and investment in fixed assets. The unemployment rate also remained at a relatively high level, which resulted in a decrease in the dynamics of retail sales of consumer goods. The situation improved in subsequent periods. A much higher rate of economic growth resulted in an improvement in the labour market and, consequently, in an increase in consumer demand. A clear symptom of improvement was also a general increase in investment outlays and a relatively high profitability of enterprises.

The current condition and development perspectives of the sector or industry in which the enterprise operates are also important in the context of divestment decisions. The Polish clothing sector is one of the largest in Europe and its size is systematically growing. According to Statistics Poland (2018), the number of enterprises engaged in the production of clothing amounted to 20.3 thousand entities in 2017. The largest and most recognizable producers include Bytom, LPP, Warmia, GETEX, Telimena, DCG, Vistula Group (Question Mark Biuro Badań Społecznych).

Considering the economic performance of the clothing companies, the growing volume of production deserves attention. In 2017, it amounted to PLN 11.4 billion, which means an increase of over 23% compared to 2012 (Statistics Poland, 2018). This increased sales revenues and profitability of enterprises. It is also worth emphasizing the increase in the value of fixed assets, which is the result of investment.

Growth prospects for the analyzed sector (in Poland as well as globally) are also important. It is forecasted that the total value of global retail clothing will amount to USD 1.660 billion in 2021, which seems to be crucial for the export of Polish products. According to PKO Bank Polski (2017) the main growth factors include rapidly changing consumer preferences, the development of online distribution channels, fashion for an ecological lifestyle, as well as an increase in the demand for sportswear.

The development of the Polish clothing sector is reflected in the financial condition of enterprises, on which the scale and extent of divestments depend largely. The analysis of the financial performance of companies was made using liquidity, debt and profitability ratios. The results of the analysis are presented in Table 2.

Source: the Author, based on the financial statements of the analyzed companies.

The analysis indicates the varied financial condition of the companies. In most cases, the analyzed ratios were at acceptable levels. This situation also took place in 2012-2013, i.e. in a period with a relatively low economic growth. However, attention should be paid to the negative value of profitability ratios of some entities. This means that these companies generated losses. This is confirmed by the low level of financial liquidity ratio. This phenomenon was particularly evident in the case of Intersport company. This may indicate its difficult financial situation and be an impulse to take divestment actions.

Another research problem was the volume of divestments operations. The analysis was conducted using the gross value of long-term assets divested, including fixed assets, intangible assets, and long-term investments (tangible and financial). Additionally, the amounts of inflows from the disposal of the indicated assets have been analysed.

Table 3: Divestments in the analyzed companies in 2012-2018 (in PLN million)

Company name	Category	Year

Source: the Author, based on the financial statements of the analyzed companies.

In the analyzed period, a different level of divestment activity of each company was noted. The highest value of assets divested took place in 2015 (PLN 552.6 million), which was the result of significant divestments made by LPP company. The intensity of divestment was also different. The upward trend took place in 2012-2015 and 2017. In contrast, declining in 2016 and 2018. The object of divestment were mainly fixed assets. To a much lesser extent, the process involved intangible assets and long-term investments (tangible and financial). The fact that fixed assets constituted the dominant share in the fixed assets structure of the analyzed companies was of significant importance. The sale of assets was the dominant form of divestment. Total revenues obtained in this way amounted to slightly

over PLN 700 million, of which over 62% were divestments of the aforementioned LPP company. To a lesser extent, the analyzed companies liquidated or transferred individual assets to subsidiaries.

The data contained in table 3 were supplemented by an analysis of the divestment activity of the companies. The following ratios were used:

- the gross value of divestment to total value of long-term assets,
- the gross value of divestment to net revenues from sales,
- inflows from the disposal of long-term assets to negative cash flow from investment activities.

Table 4: Divestment ratios for the analyzed companies in 2012-2018 (%)

Source: the Author, based on the financial statements of the analyzed companies.

The analysis shows that a relatively small part of assets was divested. The level of the first ratio did not usually exceed 10%, which indicates a limited activity of enterprises in this field. The exceptions were LPP and Solar Company, which maintained the analyzed indicators at a fairly high level. The observed trends were also reflected in the results of the analysis of the next ratio. The value of fixed assets divested was small in relation to the sales revenues.

The subject of the analysis was also the degree of coverage of investment expenditure with cash obtained from divestment. In this way, the issue of divestment was considered as a source of financing the investment activities of the enterprise. Particularly noteworthy are the companies Intersport, Lubawa, Solar, VRG, and Wojas companies, which are characterized by a fairly high value of the analyzed ratio. This proves the importance of divestment as a source of investment financing in the analysed companies. It should be emphasized that the vast majority of companies were characterized by high investment activity. This is indicated by an increase in the value of long-term assets and negative net cash flow on investing activities. Thus, the theorem that divestment is an operation accompanying the implementation of investment projects is confirmed.

The high volatility of individual ratios as well as the value of divestments and the inflows obtained in this way are noteworthy. It seems to confirm the lack of regularity of actions taken in the indicated area of business activity, described in the theoretical part of the article.

Conclusions

Long-term assets management is one of the key areas of corporate finance. It is reflected in the effectiveness of the use of assets and optimization of their value and structure, taking into account the specificity and scope of business operations. One of the possible actions taken in this field is the divestment.

The purpose of the research was to determine the scale and character of the divestment operations undertaken by companies in Poland. The research indicated a diversified activity of the analyzed companies in this field. Assets disposed of usually constituted a small percentage of long-term resources so that divestments did not have a significant impact on the value and structure of assets in each company. It is also important that the analyzed period was characterized by good economic conditions, conducive to run business. This concerned both – the general economic situation of Poland and the situation in the clothing sector. This was reflected in the good financial condition of most of the analyzed companies. Favourable economic conditions strongly encouraged companies to undertake investments rather than reducing their assets. In this situation, divestments were mainly the result of the reproduction of used assets than the reaction of companies to the difficult economic situation.

The object of divestment operations were mainly fixed assets. A much smaller percentage was constituted by intangible assets and long-term investments - tangible and financial. Undoubtedly, this is due to the specific assets structure of companies operating in the clothing sector. These are production enterprises, and therefore units in which fixed assets are a fundamental resource the operations.

The basic form of divestment was the sale of assets, thus being an additional source of capital for companies. In this context, divestments were widely described in the literature form of financing the enterprise's activities. To a much smaller extent, divestments were made by the liquidation of assets or transfer to subsidiaries.

A review of the literature and the results of the conducted research indicated the multifaceted nature of divestment. This problem is reflected in key management areas, such as optimization of the size and structure of assets, company restructuring under bankruptcy threat, business financing and enterprise capital structure management in a broad sense. The effectiveness of divestment significantly contributes to the achievement of the primary goal of financial management, which is the increase in company value.

Abstract

The article reviews the energy situation in Poland and the selected world and the European Union countries in times of dynamically growing energy demand. The conducted analysis indicates the short-term sufficiency of fossil energy sources and the negative impact of the extraction and use of fossil energy resources on the quality of air. In order to counteract global warming and climate change caused by high emissions from the energy sector, in line with the international agreement, referred to as the Kyoto Protocol (2005), many countries have obligated to reduce greenhouse gases, which are the main cause of the global warming of the Earth's atmosphere and serious climate anomalies. The European Union has become an advocate of a low-carbon economy. In the energy and climate package (adopted in 2008), it obliges the Member States to adapt their energy policy which entails reducing greenhouse gas emissions by 20%, increasing the share of energy produced from RES by 20%, and reducing energy consumption by 20%. The European Union has taken decisive steps to work on sustainability, namely by diversification of energy deposits at risk of exhaustion, economical management, climate protection, gradual independence from a single supplier and building a common internal energy market. The priority of the EU energy policy is to ensure the energy security for the Member States by diversifying supplies and decarbonising energy production. It is believed that renewable sources have become a perfect alternative to coal energy, therefore in the near future we can expect the energy transformation in many European and world countries.

Keywords: Energy, Electricity, Demand, Energy Production, Energy Consumption, Fossil Energy Sources, Renewable Energy Sources, Diversification of Energy Sources, Energy Security, Energy Transformation.

Introduction

In the second half of the twentieth century electricity became a universal form of energy. Thanks to its numerous advantages it not only radically changed industry, transport and construction but also facilitated running households. Noticeably, modern civilization uses an increasing amount of electricity. It is caused by the growing number of population and also the economic growth. Accordingly, the United Nations has forecast that in 2056 the population of the world will rise up to 10 billion (for 2020 it is 7.8 billion). It has been also claimed that the increasing demand and the growing consumption of electricity have become the reasons for diversification of energy resources. The World Energy Council has informed that our generation has already used more energy than all former generations in the past all together. Consequently, in order to provide energy security and climate neutrality for future generations, the new trends in energy policy have emerged.

Main part

1. The world energy situation

In the report "World Energy Outlook 2016," the International Energy Agency (IEA) forecasts the increase in energy demand in all regions of the world. The largest increase at the level of 90% of the projected increase in world demand will come from non-OECD countries, and 60% of this growth will come from China, India and the Middle

East. Until 2035, the demand for energy from all sources will grow with an average annual growth of 1.3%. Fossil fuels (oil, gas, coal) will remain the main source of energy (IEA, 2016).

After three consecutive years of decline in the global demand for coal, since 2017 the demand for this raw material has increased and in 2018 amounted to 1.1%. In other words, production of electricity from coal reached the highest level in history in 2018. Coal remained in the first position as a raw material from which 38% of electricity is produced on a global scale. In 2018, we could observe a significant increase in coal production (by 3% compared to 2017). Four of the six largest coal producers in the world have increased production, and three of them India, Indonesia and Russia have achieved their highest levels of coal production in history. Two of them, Russia and Indonesia recorded the historically highest rate of raw material exports to third markets. In India and Southeast Asia, the demand for coal is projected to grow by around 5% per year (mainly in Vietnam and Indonesia) (IEA, 2017).

In the world, over the next five years, the demand for coal will remain at a stable level, as the declines observed in the USA and the European Union will be offset by the growing demand in India and other Asian countries.

In China, which is the largest producer and consumer of coal in the world, demand for this raw material will peak in 2022. This growth is forecasted to be mild and only domestic policy (the place of renewable energy and nuclear energy in the Five-Year Plan) will determine the future demand for coal. The consistent shift of the coal industry from Europe, and even from the USA, to Asian countries: China, India, Indonesia is associated primarily with the increase in population and the large economic development expected in those parts of the world (A. Strupczewski, 2017).

In the US the future of the mining sector depends on the further development of the shale gas sector. The high level of natural gas supply in the internal market together with the adopted environmental protection policy will contribute to a decline in demand for coal at the level of 4% annually by 2024. The share of electricity production from coal will drop to 21% in 2024. Australia and South Africa will maintain the current level of coal exports to foreign markets, while Russia will gradually redirect its production also to Asian markets.

It is forecast that the demand for natural gas will increase by 1.7% per year, for energy obtained from water 2.1% per year, and for energy obtained from other renewable energy sources by 7.8% per year. The agency estimates that by 2040 the global demand for electricity will increase by 40%. The pace of overall consumption growth will be gradually curbed by high prices and new energy policies, potentially leading to a stabilization of this demand. Almost 60% of global energy generated in 2040 will come from renewable energy sources, half of it will come from wind and sun. The increase in the share of renewable energy sources may mean the end of the demand for coal (M. Bartosik, 2015).

The International Energy Agency (IEA) in its “World Energy Outlook 2016” forecasts a rising significance of the position of natural gas in world energy production. Due to the large supply, low prices and low emissions of CO_2, gas will reach the 25% share in meeting the demand for energy and will become the second (after crude oil) most important fuel in the global energy balance. The demand for this fuel will increase by more than half, the fastest rate of all fossil fuels. On the other hand, unconventional gas, despite criticism regarding the environmental consequences of drilling processes, will account for almost 60% of global production growth. According to WEO (World Energy Outlook) forecasts, Russia and China will be the largest producers of GAS by 2035 and Europe will remain the largest importer on the global gas market until 2035, with a demand of 540 billion m^3 in 2035 (IEA, 2016).

Almost 90% of the expected increase in long-distance gas trade will be provided by liquefied natural gas (LNG) by 2040. New liquefaction capacities will be developed mainly in the USA and Australia and in Russia, Qatar, Mozambique and Canada.

According to the report “World Energy Outlook 2017” it is predicted that in 2040 electricity generation will be almost completely decarbonised. It will be based on renewable energy sources (over 60%), nuclear energy (15%) and the contribution from CCS technology (6%), which will play an equally important role in reducing emissions from the industrial sector. Low-emission sources will double their share in the energy balance – to 40% in 2040 (IEA, 2017).

It is expected that despite the fact that some countries will withdraw from nuclear energy, the nuclear sector will increase the energy production. Globally, the installed capacity in nuclear power plants will increase to 630 GW (in 2035) mainly in China, India and Russia which plan to turn on about 200 GW of new capacity.

Based on data obtained by International Energy Agency, we observe a systematic increase in the importance of renewable energy. It is predicted that in 2035 global wind power production in onshore locations will increase to almost 590 TWh (mainly in China), and in offshore locations energy production will increase to 670 TWh (mainly in China, the US and the EU).
A significant increase in solar electricity production is also forecast, with an average annual increase of 15% (mainly in China, Japan and India). There has also been a sharp increase in the hydropower sector in countries outside the OECD.

According to the report "Electricity for Generations" in 2016, alternative energy sources in the form of renewable energy sources (RES), with their almost 14% share in meeting the global energy demand, are not yet able to replace fossil fuels, both from technical and technological, as well as economic reasons. However, the decline in the prices of renewable energy and the subsidies introduced by many countries mean that global investments in renewable energy sources have been systematically growing since the beginning of the 21st century (II Congress of Polish Electrical Engineering, 2015/16).

Energy production and consumption are responsible for two-thirds of the world's greenhouse gas emissions. In order to counteract climate change caused by harmful emissions, many countries have made commitments to reduce their CO_2 emission to meet the previously set goal of keeping the global average temperature increase below 2 Celsius degrees in relations to pre-industrial level. In the opinion of the IEA, in order to counteract serious climate anomalies, keeping the global temperature increase below 2 °C requires investing USD 300 billion in renewable energy and USD 1,000 billion in energy efficiency, as well as the global reduction of CO_2 emissions by a quarter.

According to the UN indications, reducing the current level of global carbon dioxide emissions to the atmosphere by at least 50% by 2050 requires the implementation of new technologies limiting its emission, reducing energy consumption by improving the efficiency of its use and looking for alternative energy sources. According to the Agency's data, last year the increase in emissions in a number of countries was offset by their decline in the most developed economies. The US recorded the largest decrease in CO_2 emissions in history – by 2.9%. In the EU, emissions decreased by 5%. In Japan, emissions decreased by around 4%, it was the fastest decline since 2009. The main reason for this decline is the increase in nuclear electricity generation. Overall, economically developed countries have observed the 15% reduction in CO_2 emissions (IEA, 2017).

The most rational strategy which may support economic growth and the protection of the environment, in a global context, in particular by reducing greenhouse gas emissions contributing to climate change, is based on the following actions:

- diversification of energy sources,
- increasing the efficiency of energy consumption in industry, buildings and transport; - gradual reduction in the use of the least efficient coal-fired power plants and ban on their construction.
- increasing investments in electrical energy technologies (electricity generation and processing) based on renewable energy sources in 2030;
- phasing out of fossil fuel subsidies to end-users by 2030;
- reduction of methane emissions from oil and gas extraction,
- development of energy-saving technologies for the use of all types of energy.

The World Economic Forum (WEF) published the report ("Fostering Effective Energy Transition") which evaluated the current state of the energy sector and the readiness of 115 countries for the energy transformation, understood as "transition to a safe, sustainable, affordable and inclusive energy system," which in practice, means moving away from non-renewable sources (such as oil, gas and uranium), saving energy and increasing energy efficiency (World Economic Forum, 2019).

The main conclusions of the research are not optimistic since the pace of energy transformation in the world is slowing down and currently it is the lowest in five years. In the ranking made by the WEF, Poland was placed on 75th position next to Ghana, Bulgaria and Russia, due to the lowest diversification of energy sources in the European Union.

The top ten in the ranking was dominated by Western and Northern European countries with Sweden, Switzerland and Norway at the fore. Countries at the top of the ranking owe their results to various energy sources (including their own natural resources) and the structure of the energy system. Moreover, their prospects for the future were highly rated, namely the strong institutional and regulatory framework, an innovative business environment, and a high level of political commitment to the energy transition.

Zimbabwe, South Africa and Haiti close the WHO ranking. In the evaluation the strong involvement of energy sectors in consumption, large exports of solid fuels (oil and coal), the lack of an effective regulatory framework enabling transformation, as well as political instability were emphasized.
In 2025, RES will become the world's largest energy source. Global production of electricity from renewable sources, including hydropower, will outperform coal production. It is predicted that in 2025, renewable energy sources will provide about one third of the world's electricity production, half of this amount will be generated in hydro power plants, and the rest mainly in wind and solar power plants. The total installed capacity of solar sources is to exceed the capacity of gas sources in 2023, and coal sources a year later. (Renewables 2020 Report IEA).

The IEA expects that the climate neutrality targets announced by an increasing number of new EU and Asian countries will result in accelerating the use of renewable energy. The agency reminds that Japan and South Korea want to achieve net zero emissions in 2050, and China in 2060.

2. Energy situation in the European Union

All European Union member states conduct their own energy policy, its main goal is to ensure energy security. This policy is influenced not only by solutions adopted in the energy sector at the Community level, but also by each country's energy resources, access to fossil fuels, as well as geographic and social conditions.

Ecological aspects, supported by political decisions, play an important role in shaping the consumption structure of primary energy carriers in the EU countries. The European Union, being a fervent supporter of the ratification of the Kyoto Protocol to reduce greenhouse gas emissions and stop the process of Earth's climate change, consistently strives to reduce the share of carbon in the consumption structure of primary energy carriers and to increase the share of renewable and low-emission energy carriers – biomass, hydropower, wind energy, nuclear energy, as well as the relatively low carbon fossil fuel natural gas.

The demand for electricity from coal in Europe is significantly decreasing. The reasons for this are the rise of CO2 limits prices and the decrease in the prices of gas. The share of hard coal in the EU mix fell by as much as one third. Renewable energy sources and natural gas are gradually replacing coal. In 2019, 35% of energy in the European Union countries came from RES. The EU energy mix in 2019 was as follows: RES 34.6%, nuclear 25.5%, gas 21.7%, lignite 7.8%, hard coal 6.8%, other raw materials 3.6%. 2019 was a record year for new RES capacities: wind 13.4%, water 10.8%, biomass 6.2, sun 4.2 (IEA, 2020).

By 2030 European Union countries are expected to increase the consumption of natural gas by 8% and the low-emission carriers – renewable sources by 5%. In the next 10-15 years, natural gas has to become the main primary energy carrier used for electricity production. At the same time, the consumption of coal is going to decrease by 4%, crude oil consumption will drop by 1% and nuclear energy will decrease by 7% (P. Kwiatkiewicz, R Szczebrowski, 2015).

The dominant energy sources in the EU economy are natural gas and crude oil (predominant in transport). In total, these sources account for over 60% of primary energy consumption. Unfortunately, due to the scarce resources of these energy sources, the European Union is becoming dependent on the import of these raw materials from other regions of the world. Remarkably, LNG is also strengthening its role. The largest gas exporters to the EU are Qatar, Russia and the USA. For ecological and climatic reasons, coal is becoming a fuel of declining importance, and its former status can be restored only by clean coal combustion technologies.

The European Union has set ambitious climate targets for the economies of the Member States in the field of renewable energy development, reduction of greenhouse gas emissions and improvement of energy efficiency. The EU is to become a climate neutral economy. In ambitious plans until 2050. 80% of electricity in the EU will come from renewable sources. Noticeably, extensive support was provided for the development of RES. The member states have developed financial support systems for the development of renewable energy sources (i.e the system of certificates in force in Poland or the system of guaranteed electricity prices in force in Germany). The intensive development of renewable sources and their preference in the power system resulted in permanent changes on the energy market.

The promotion of renewable sources has significantly influenced the development of prosumer energy. One could observe the dynamic increase in the power installed in distributed micro-sources (mainly photovoltaic). The development of microgeneration and the increase in the number of prosumers resulted in the displacement of energy based on fossil fuels from the system and a reduction in the demand for electricity. It is claimed that the lower demand for energy resulted from the fact that majority of prosumers have covered their needs on their own.

In 2016 the European Commission presented a proposal to reform the energy market in the EU in the form of a "winter package" or a "clean energy" package. For Poland, it is an opportunity to reform the market and modernize the sector in line with global trends in reducing emissions, greater care for the environment and providing consumers with high-quality services, due to the real competition on the market. The European Union is moving towards 3D energy, i.e. decentralized, digitized and decarbonised. It is planned to release prices for individual consumers in 2021. Facilitations for the development of prosumers in single- and multi-family houses and prosumers-entrepreneurs will be created. By 2025, the target of 70% of transmission capacity on power interconnectors made available for cross-border exchange will have to be achieved. The role of DSOs will change radically; distributors will be responsible for integrating local resources (RES, storage facilities, DSR) into the energy system. An EU institution will be established to coordinate the work of the DSO (Distribution System Operator).

The main goal of the proposed changes is to accelerate the development of renewable energy sources with the planned 27% share of RES in EU energy production and to improve energy efficiency by 27% by 2030. Furthermore, the EU climate and energy policy obliges Member States to introduce a new ETS system leading to gradual reduction of CO_2 emission.

In accordance with the provisions of the Winter Package, in 2030 the power market support for power plants emitting over 550 g of CO_2 per kWh will end, which in practice means the elimination of public support for coal-based energy. The European Commission decided also to set a goal for transport; in this field a renewable energy share should be at the level of 14% for each country.

What distinguishes European Union countries is a large share of imports to meet the needs of most fossil fuels. Forecasts indicate that in 2030 the dependence of EU countries on the supply of raw materials and energy fuels may increase up to 70%. The reason for this is the continuous increase in the energy demand.

In order to ensure the highest possible level of energy security of the Member States, the EU is trying to introduce a number of legal regulations to prevent crises in the energy sector. The most important legal act concerning security of supply is Council Directive 2006/67 / EC of 24 July 2006. It obliges Member States to maintain minimum stocks of crude oil or petroleum products.

An important factor enabling the stabilization of supplies to the EU countries is the marketization of European energy exchange and the creation of a single energy market, protecting individual countries against pressure from third countries. Liquefied natural gas (LNG) imported into the EU by a new supplier from the USA is gaining importance.

The current principles and objectives of energy policy are based on the Maastricht Treaty (signed by the member states in 1992). It introduced provisions on the creation of a single energy market as part of a single internal market that would ensure the free movement of goods, people, services and capital.

The most important energy priorities of European Union are development of the common energy market, counteracting climate change and solving other key environmental problems, diversification of energy sources, promoting energy efficiency, increasing competitiveness of renewable and alternative energy sources and working on sustainability (N. Wojtowicz, 2014).

The common EU energy policy is to ensure that all member states achieve three main goals, which are:

- energy security
- minimizing the risk and the impact of a possible collapse of energy supply on the economy and society of the European Union,
- competitive energy systems
- ensuring low energy costs for producers and users from the point of view of industrial competition and the implementation of broadly understood social goals,
- protection of the natural environment integrated with both the production and use of energy to maintain the ecological and geophysical balance of nature.

The most important mega trends in the European energy sector include falling costs of energy generation from renewable sources, reducing the impact of energy on health and climate (reducing emissions), the changing role of coal, improving energy efficiency and emerging new business models in the energy sector (new possibilities in generating and distribution of energy, development of distributed energy, development of competition not only in production and trading, but also in transmission and distribution of energy) (IEA, 2020).

3. The energy situation in Poland

Two main fuels play a significant role in the structure of electricity production in Poland – hard coal and lignite, which together are responsible for the production of nearly 73,6% of electricity (in 2019). The share of other fuels is very small; for gas and biomass, water and wind energy it amounts 3%. The generation side of the Polish energy system is the least diversified in the entire European Union.

According to the data of the European Coal and Brown Coal Association, in 2017 as much as 27% of European coal was mined in Poland. This country is not only the largest producer (second to Russia in Europe) of hard coal in the European Union (65,5 mil tons) but also consumer of coal (73,8 mil tons). In 2014 proven coal reserves accounted for 0.6% of world reserves, annual coal production was 1.4% of world production, and annual coal consumption accounted for 1.4% of world consumption.

The sufficiency of the currently available hard coal resources in Poland was estimated at 40 years, and with the use of new technologies in the extraction of coal from deeper and deeper deposits (not yet developed), it was estimated at approximately 100 years (data of the Polish Geological Institute of 2014). The statistical sufficiency of lignite at the current level of extraction was estimated at approximately 200 years.

It is estimated that by 2030 hard coal and lignite will remain the basis of the Polish energy mix, although their share will gradually decrease (R. Macuk, J Maćkowiak-Pandera, A. Rubczyński, 2018). Surprisingly, one can observe a certain paradox of the domestic energy market; despite the constant high demand for this raw material (an increase in 2007-2017 by 12%), its extraction in mines is decreasing (high extraction costs). At the same time, some of the coal extracted in Poland is not directed to its recipients, but it is stored on dumps since domestic coal is more expensive and often of lower quality than imported coal. Hence, almost 20% of domestic production is supplemented with coal imported from Russia (50% of supplies), Colombia, the USA and Kazakhstan.

Most likely, in 2030 Poland will produce 60% of electricity from coal (in 2017 it is 86%), and among other raw materials in the energy generation structure, there will be gas and renewable energy sources, which will be largely provided by wind farms built on the sea (A. Strupczewski, 2017).

The total documented gas reserves in Poland in 2014 were estimated at 0.1 Tm^3 (which represents 0.1% of world reserves), annual gas production at 4.2 Gm^3 (which constitutes 0.1% of world production), and its sufficiency for 23.6 years. The annual gas consumption was estimated at 16.3 Gm^3 (which constitutes 0.5% of world consumption).

According to the data obtained by the Ministry of Economy, the share of gas in the Polish energy mix approached 9%. On average about 30% of gas consumption in Poland is satisfied from domestic deposits, about 50% the annual consumption comes from Russia. The rest is mainly imported from Germany and the Czech Republic. 2016 brought a particularly important event on the Polish natural gas market – the LNG terminal for liquefied gas in Świnoujście started operating. Two storage tanks accommodate 320. 000 m^3 of gas imported from the United States. In 2016, the share of gas imported to Poland increased to 84%.

Polish new energy policy to 2030 assumes acceleration of the development of renewable energy sources, so that by introducing low-emission energy sources we can achieve a decrease in the average emissivity of energy production and meet the standards presented by the European Commission in the draft Winter Package (planned 27% share of RES in energy production to 2030, end of capacity market support for power plants emitting more than 550 g CO_2 per kWh). The limit of carbon dioxide emission defined in the project actually means the end of public support for coal-based energy.

Poland has made substantial progress in developing RES. The share of renewable energy sources in electricity production in 2019 was the highest in history and amounted to 15.4%, but it is still too low to meet EU obligations (over 43% share in the energy mix in 2030). Much in this regard may depend on political decisions, funding strategies and appropriate regulations (G. Maśloch, 2018).

In 2017, according to the ERO data, wind farms dominated the RES structure in Poland in terms of installed capacity and it is nearly 68.5%. Biomass sources were in second place with a share of almost 16%, and hydropower plants in the third place with a share of almost 11.6% (ERO, 2017).

The report “8 ways to integrate RES. System security against the growth of variable sources," made for the Energy Forum by experts from the international consulting company called Ecofys is aimed at presenting the main fields that may facilitate further integration of variable energy sources in the context of the changing energy system of Poland. They are as follows:

1. modernization of transmission networks and generation assets;
2. increasing the flexibility of the energy system (quick response to changes in supply and demand);
3. increased flexibility of conventional power plants;
4. linking the energy sectors (electricity, heat and transport);
5. energy storage as a future partner for renewable energy;
6. optimal distribution of RES installations;
7. network expansion and integration with neighboring markets; 8. development of short-term markets.

Until 2030 The European Commission has set a 55% greenhouse gas reduction target for its member states. Poland's contribution to achieving this goal should amount between 44 and 51% reduction of greenhouse gases (compared to 1990). By 2050, the Polish energy sector should become climate neutral.

Over the last ten years Polish power industry has changed considerably. The changes that affected Polish and in the past European energy sector mainly concern new trends in the conventional generation, distribution and the sale of energy. It appears that the transition from conventional, centralized energy to decentralized energy based on renewable sources (photovoltaics and wind energy) is inevitable due to decline of fossil resources and high financial outlays which have to be incurred for the modernization of power units and the need to purchase CO_2 emission allowances. It was estimated that nuclear energy would emerge after 2022 – the Ministry of Economy in the fourth stage of the "Polish Nuclear Power Program" project (01/01/2016 - 31/12/2022), planned the construction of the first unit of the first nuclear power plant in Żarnowiec. Unfortunately, according to recent data, the next (included in the Polish Energy Policy until 2040) date for commissioning the first nuclear unit in 2033 seems less and less realistic.

Poland's energy policy to 2030

The document “Energy Policy of Poland to 2030” includes a forecast of final energy demand in 2006-2030. It is expected that the final consumption of electricity will increase by 55%, gas by 29%, district heat by 55%, petroleum products by 27%, renewable energy by 60%. Such high increase in the consumption of renewable energy results from the need to meet the requirements of the European Union's Energy and Climate Package, adopted in December 2008 (Ministry of Economy, 2009).

As part of the package, the European Union has set quantitative targets for 2020, the so-called 3 x 20%, *i.e.* the 20% reduction in greenhouse gas emissions compared to 1990, the 20% reduction in energy consumption compared to the EU's forecasts for 2020, increasing the share of renewable energy sources to 20% of total energy consumption in the EU, including increasing the use of biofuels in transport to 10%. Meeting the energy policy target of 15% share of renewable energy in the gross final energy structure in 2020 will be possible as a result of the accelerated development of the use of all types of renewable energy sources especially the wind energy.

The demand for final electricity will increase until 2030 with an average rate of 1.6% per year. The highest increase in demand for final electricity among economy sectors is forecasted in services (by 62%) and households (by 48%). The demand in industry will increase by 35%, while in agriculture it will remain virtually unchanged. In the structure of primary energy carriers, a decrease in the consumption of hard coal by approximately 16.5% and lignite by 23% is expected, with a simultaneous increase in gas consumption by approximately 40%.

Achieving EU renewable energy targets will require gross electricity production from RES in 2030 at approximately 18.2% of total production. The largest share of energy from wind farms will be about 8.2% of the estimated gross total production. Net electricity production is projected to gradually increase by around 41% by 2030.

The Polish energy sector is currently facing serious challenges. The constantly growing demand for energy, depletion of natural resources, increasing dependence on imported raw materials, fluctuations in the prices of energy resources and increasing environmental pollution require a new approach to energy policy. The fundamental goal of this policy is to improve and develop exhaustion and consumption renewable energy. Due to the small share of renewable sources in electricity production in Poland, it is the responsibility of the national authorities to support the development of renewable energy sources.

The main goals of the state's energy policy, which are part of the strategy for the development of renewable sources in Poland are included in Annex 2 to the Polish Energy Policy to 2030. They are as follows:

1) an increase in the share of renewable energy sources in final energy consumption to at least 15% in 2020 and a further increase in this indicator in the following years;

2) achieving a 10% share of biofuels in the transport fuel market in 2020 and increasing the use of second-generation biofuels;

3) protection of forests against overexploitation in order to obtain biomass and sustainable use of agricultural land for renewable energy purposes, including biofuels, so as not to lead to competition between renewable energy and agriculture and to preserve bio-diversity;

4) increasing the degree of diversification of supply sources and creating optimal conditions for the development of distributed energy based on locally available raw materials.

The adopted goals are supposed to be achieved through the implementation of the following activities:

1) obtaining the 15% share of renewable energy sources in the final energy consumption in a sustainable manner, divided into individual types of energy;
2) maintaining support mechanisms for producers of electricity from renewable sources (*e.g.* through certificates of origin);
3) maintaining the obligation to gradually increase the share of biocomponents in transport fuels;
4) construction of agricultural biogas plants, assuming the creation of an average of one biogas plant in each commune by 2020;
5) maintaining the principle of exemption from excise duty on energy from renewable sources;
6) support for the construction of new renewable energy units and power grids;
7) development of the industry producing devices for renewable energy;
8) development of new technologies and construction of installations for obtaining renewable energy.

Summary

The Polish energy policy which has implemented the main objectives of the European Union energy policy, promotes activities aimed at increasing the production of energy from renewable sources, and it also involves the more rational use of electricity, as well as protection of climate and environment. The use of renewable energy sources will create conditions for the development of energy based on locally available raw materials, it will reduce the emission of pollutants, it will limit the destructive effects of energy on the environment, it will cause a greater degree of independence from imported energy supplies and it will also increase Polish energy security. Building the internal energy market in the European Union and implementing a common energy policy is going to reduce the risk of collapsing energy supplies and to remove the threat of an energy crisis.

Transformation in the energy sector in Poland, similarly to other European Union and world countries is already a fact. In the ongoing transformations, the most important issue is the transition from centralized energy, based on conventional energy, towards distributed energy, using mainly renewable energy sources from local and regional resources. Noticeably, electricity demand and consumption continue to rise, especially in developing countries. Demand for coal has shifted from Europe and the US to Asian countries. In order to counteract dangerous climate anomalies, a increasing number of countries declare their will to achieve the climate neutrality. It might be stated that for the Polish and EU energy sectors it will be 2050.

Resumen

Identificar los costos de la atención médica es un paso esencial para la planeación estratégica en la administración y prestación de servicios de salud. En esta investigación se busca identificar y analizar los costos sociales y de la atención en salud del embarazo en Colombia tomando como caso tipo a una mujer saludable en edad media sin complicaciones a lo largo del embarazo y hasta el alumbramiento, comparando al mismo tiempo lo que cuesta en ciudades grandes y en ciudades intermedias y zonas desprotegidas socialmente como Putumayo, Nariño, Cauca, Guaviare, Sur de Bolívar, Sur de Tolima, Bajo Cauca Antioqueño y el Catatumbo.

Esta investigación toma relevancia una vez se evidencia la gran cantidad de embarazos que llegan a término Colombia, año a año, esto a pesar de la visible disminución de la tasa de natalidad general en el país. Evidenciar los costos de la atención médica del embarazo puede incitar a las Administradoras de Planes de Beneficios (APB) e Instituciones Prestadoras de Salud (IPS) a general planes para promoción de la planificación adecuada del embarazo, además de encontrar bases académicas para realizar la negociación de tarifas correspondientes al pago de la atención médica del embarazo.

La metodología a utilizar es de tipo mixto y transversal, que permitirá identificar los costos directos e indirectos del embarazo en Colombia, asumiendo, para este caso, que los costos directos se relacionan con los costos de atención del embarazo y que los costos indirectos son los costos sociales asociados al embarazo. Se espera identificar los costos de la atención médica del embarazo y determinar los costos sociales del embarazo y analizar la relación que existe entre ambos costos.

Palabras clave: Embarazo, costos en salud, análisis de costos

Planteamiento Del Problema

Colombia actualmente enfrenta diversos de problemas de Salud Pública. Algunos se han mantenido a lo largo de las últimas décadas, y han tomado relevancia gracias a los acuerdos internacionales que velan por la defensa de los derechos humanos, entre estos cabe mencionar los Objetivos de desarrollo del milenio y los actuales Objetivos de Desarrollo Sostenible. Uno de estos objetivos está relacionado con mejorar la salud materna e infantil, para lo cual, es necesario mejorar la cobertura y el seguimiento, desde la concepción hasta el alumbramiento, de todas las mujeres que se embarazan en el país.

Diversas políticas públicas abordan la natalidad en el país y sus resultados se pueden observar en la notable disminución de la tasa de fertilidad del país, pasando de 6,7 nacimiento por mujer en 1960 a 1,8 nacimientos por mujer en 2017 (World Bank Group, 2019). Por su parte, la razón entre tasa de natalidad de mujeres de entre los 15 y los 19 años y tasa de natalidad general, ha aumentado de 3 a 4,4 (World Bank Group, 2019), es decir que por cada hijo de mujeres adultas se espera 4,4 nacimientos de adolescentes.

Uno de los vacíos existentes dentro del actual sistema de salud de Colombia es la ausencia de ejercicios de costeo que permitan determinar los costos reales de las atenciones de salud. Esto, dado que la contratación que se realiza en el

país entre ABS e IPS está fundamentada en los dos manuales tarifarios autorizados para la realización de negociaciones y acuerdos entre estos dos agentes del mercado, siendo estos, el Manual ISS (Instituto de Seguros Sociales, 2004) y el Manual SOAT (Presidente de la República de Colombia, 2006).

Cuantificar adecuadamente los costos del embarazo en Colombia de la mano con los protocolos establecidos por la normatividad colombiana y de los manuales tarifarios a las entidades de salud permitiría realizar presupuestos más acertados frente a la atención de los servicios de salud relacionados con mujeres embarazadas en Colombia.

Por último, el cálculo adecuado de los costos unitarios de la atención médica y los costos sociales del embarazo en Colombia puede evidenciar los gastos que implican dicha atención con los niveles actuales de natalidad del país y que se podrían disminuir significativamente si se aplicaran políticas públicas más fuertes en términos planificación de la reproducción.

De este contexto surge la pregunta: ¿Cuáles son los costos administrativos y de la atención médica del embarazo en Colombia?

Antecedentes

Los costos encuentran diversas definiciones que buscan diferenciarlos de los gastos a la vez que caracterizarlos y clasificarlos de diversas maneras. Una definición administrativa afirma que "el costo de un objetivo perseguido estará dado por el valor, medido en términos monetarios, de los otros usos que se podrían haber dado a los recursos económicos utilizados para conseguirlo" (Corrales, Frías, & Lobo, 2014). Otra perspectiva menciona que "El costo corresponde al valor del consumo de recursos en que se incurre para generar un servicio, el cual puede ser económico o financiero" (Lenz-Alcayaga, 2010).

El proceso general para realizar un ejercicio de costeo es "a) identificar todos los recursos utilizados para obtener el producto o servicio; b) analizar qué otros usos pueden tener; c) identificar sus valores en términos monetarios; y, luego; d) sumar todos estos valores para encontrar, de esta forma, el costo del producto" (Corrales, Frías, & Lobo, 2014).

Algunas de las clasificaciones que presenta la bibliografía sobre los costos presenta los costos de producción, distribución y administrativos, directos e indirectos, fijos y variables, totales y unitarios, históricos y predeterminados, controlables y no controlables, relevantes y no relevantes, desembolsables y de oportunidad, entre otros (Castrillón, 2010). Los costos directos son descritos como aquellos que son directamente asociados a la prestación de un servicio, un producto o una división, mientras que los costos indirectos están asociados a una división, pero son indirectos al producto o servicio (Castrillón, 2010). En el caso de los estudios que analizan costos por fuera de una institución en salud, se suelen analizar los costos directos e indirectos, asumiendo los costos indirectos como los costos sociales.

En el caso de los costos en salud, "los costos directos se asocian con los recursos propios del sistema de salud, mientras que los costos indirectos se relacionan con el valor del tiempo que tiene que invertir el paciente en una intervención (traslado, espera, recuperación, etc.), asociado al salario y a su productividad. La economía, recomienda adoptar una perspectiva más amplia: la perspectiva social. El costo social se refiere a los costos que afectan a todos y cada uno de los miembros de la sociedad" (Lenz-Alcayaga, 2010). A pesar de la importancia que toma la cuantificación de los costos para la buena administración de una empresa, en el caso de la salud las "organizaciones no han tomado conciencia de los costos en los que deben incurrir para el tratamiento; siempre asumen que debe ser costeado por las EPS obviando sus responsabilidades" (Monsalve, y otros, 2018).

Por otro lado, el sistema de Salud en Colombia tiene como base fundamental la Ley 100 de 1993, que junto con el Decreto Único Reglamentario de Sector Salud y Protección Social (Ministerio de Salud y Protección Social, 2016), conforman una extensa normatividad para el sector, siendo fundamental la afiliación al Sistema General de Seguridad Social en Salud para la adquisición de derechos y obligaciones derivadas. Por su parte, la constitución política de Colombia establece que las mujeres "durante el embarazo y después del parto gozará[n] de especial asistencia y protección del Estado" (Pueblo de Colombia, 1991) lo que implica una cobertura obligatoria a esta población por parte del Estado, principalmente del sistema de salud.

La atención materno infantil incluye una cobertura a "los servicios de salud en el control prenatal, la atención del parto, el control del posparto y la atención de las afecciones relacionadas directamente con la lactancia" (Congreso de la República de Colombia, 1993). Por su parte, las guías de práctica clínica para la prevención, detección temprana y tratamiento de las complicaciones del embarazo, parto o puerperio, muestran la cobertura, tratamientos y procedimientos indicados para las mujeres en Colombia (Ministerio de Protección Social - Colciencias, 2013). Otros

documentos, como la guía de Control prenatal y factores de riesgo, realizada por la secretaría de salud e Bogotá (S.F.) muestran, por su parte, atenciones y cursos de acción indicados para el cuidado prenatal.

En relación al manejo de los costos en salud, la normatividad colombiana indica que las entidades de salud deben manejar un presupuesto y un sistema de costos a través de centros de costos [falta citar]. La investigación realizada por Duque, Gómez y Osorio (2009), muestra que buena parte de las entidades presentadoras de servicios de salud no cuentan con un sistema de costos ni reconocen la importancia de este para el buen manejo de los recursos.

Para el establecimiento de tarifas de pago de la presentación de servicios de salud, se utilizan dos manuales tarifarios, siendo estos el manual ISS y el manual SOAT. El primero de estos, como su nombre lo indica, fue creado para la negociación con el liquidado Instituto de Seguros Sociales, y a pesar de que su última actualización fue realizada en el año 2001, su uso está más asociado y es recurrente en las negociaciones que se realizan con entidades de salud del sector público. Su falta de actualización responde a la desaparición del ISS y obliga a las entidades que realizan acuerdos basados en este manual a aumentar un porcentaje arbitrario sobre los costos asignados en el manual, de dente el 20 y el 40%, sin tener ninguna relación directa con los costos reales de las atenciones prestadas.

Por el otro lado, el Manual Tarifario SOAT, fue creado para responder a la creciente necesidad de tener unas tarifas estandarizadas para atender los accidentes de tráfico recobrados al Seguro Obligatorio de Accidentes de Tránsito. Así, creado bajo otro objetivo, es utilizado en negociaciones entre entidades de salud dada su actualización anual. Es de aclarar que esta actualización anual se da principalmente porque sus tarifas están ligadas al SMLV, por lo que anualmente suben en la misma medida en la que aumenta el salario mínimo. En este caso, las tarifas disminuyen porcentualmente entendiendo que las tarifas que presenta el manual están por encima de los costos reales de la atención.

En ambos casos, hay una diferencia entre los objetivos por los que se desarrollaron los manuales y el uso que se les da en la actualidad. A su vez, existe un vacío en la inclusión de nuevas tecnologías, tratamientos y procedimientos en salud, que no están incluidos en estos manuales a pesar de hacer parte el paquete de cobertura del POS, o de los paquetes, alto costo, controlados y no pos.

Objetivos

Objetivo General

Analizar los costos directos e indirectos de la atención médica del embarazo en Colombia para evaluar el impacto monetario que generan los embarazos tanto en el sistema de salud como en las mujeres embarazadas y sus familias en diferentes zonas urbanas y rurales.

Objetivos Específicos

1. Determinar los principales factores que inciden en los costos sociales como costos indirectos del embarazo en Colombia
2. Identificar los factores que permiten calcular los costos de la atención médica del embarazo como costos directos para el sistema de salud colombiano
3. Comparar los costos asociados al embarazo en los dos manuales tarifarios de salud existentes en Colombia para evidenciar las diferencias de costos que ponen en desventaja a entidades en salud de acuerdo con el manual tarifario que utilicen para la negociación de tarifas
4. Identificar las acciones propuestas en guías de práctica clínica, protocolos de atención y lineamientos de política pública en relación a la atención del embarazo con miras a fortalecer los procesos de atención

Metodología

Estudio de tipo mixto transversal para la medición de costos directos e indirectos del embarazo en Colombia. Se plantean cuatro etapas:

Etapa 1: Revisión documental de metodologías de costeo desarrollados para la construcción de análisis de costos parciales y totales en salud, cálculos realizados sobre embarazo y cuidado prenatal, y documentos de práctica clínica, guías, protocolos y reglamentación relacionada. El proceso de revisión documental está compuesto por las siguientes fases: Búsqueda en bases de datos; Construcción de matriz bibliográfica; Construcción de RAES.

Etapa 2: Cuantificación de los costos indirectos (se asumen como los costos sociales del embarazo). El proceso de cuantificación de costos indirectos está compuesto de tres fases, siendo estas: Construcción de instrumento entrevista semiestructurada; Identificación de una población y muestra; Aplicación de entrevistas a la muestra seleccionada; Sistematización de la información y generación de resultados.

Etapa 3: Cuantificación de los costos directos (se asumen como los costos de la atención médica y administrativa relacionados directamente con el embarazo). El proceso de cuantificación de costos directos está compuesto de tres fases, siendo estas: La caracterización de tratamientos médicos del caso tipo; La determinación del uso de recursos; El cálculo de costos unitarios y costos totales.

Etapa 4: Consolidación de la información y construcción de resultados. Se plantea realizar la consolidación de los resultados encontrados en la Etapa 2 y 3 para cuantificar los costos del embarazo en Colombia como costos unitarios y costos globales.

Agradecimientos

A la Corporación Universitaria Minuto de Dios UNIMINUTO, quienes dieron soporte financiero al proyecto "Análisis de los costos de la atención médica del embarazo en Colombia", del cual se deriva este documento. A mi familia y amigos por su apoyo incondicional.

Inclusion of Pregnant Women in The Colombian Labor Market

Salomé del Pilar LÓPEZ-PEÑA

Corporación Universitaria Minuto de Dios – UNIMINUTO, Bogotá, Colombia
splopezp@unal.edu.co

July Paola JIMÉNEZ CALVO

Universidad: Universidad Nacional de Colombia, Bogotá, Colombia
jpjimenezca@unal.edu.co

The labor market in Colombia has been growing steadily since the economic opening that began in the 1990s, thanks to various initiatives and orientations such as the Washington Concession. This change in the labor market has meant, in addition to the well-known displacement of people from the rural sector to the urban sector, a significant increase in the country's economically active population along with women's access to the labor market. A large number of people have entered the labor market, and, with time, educational conditions have adapted to the needs of the market, allowing some of these people to study, improve their working level and consequently improve their standard of living.

However, access to the labor market has been more evident among men than women, even though the population of women is slightly larger than that of men, a trend that has increased over the years. This situation has several consequences for the country, among them, a higher rate of unemployment among women, wage inequality, wage discrimination, discrimination when in the gestation state, among others.

The indicator of unemployment of men and women as a percentage of the respective labor force shows that women have a higher level of unemployment than men, higher by 4% according to the latest data recorded by the World Bank (2018). Graph 1 shows the trend of this indicator.

Fig.1: Unemployment in men and women (as a percentage of the workforce)

Own making. Source (Banco Mudial, 2018)

The actions that have been implemented in Colombia to modify this situation are, in turn, diverse. Authors such as Buchely, propose, in addition to the traditional ways, "to adopt alternative policies such as community centers, which are the programs oriented to the social redistribution of domestic work as a way to promote the participation of women in the formal labor market with the social support of the members of their own community" (2013). The actions

carried out must take into account relevant or not relevant aspects in the labor world, such as social class, if one has children if one is married if one is a single mother, among others.

In research carried out on a sample of pregnant women in Bogotá, it was found that all of them identified pregnancy as a situation that placed them at a disadvantage in terms of work compared to other people. Some of them felt that they were relieved of some of their duties without any cause and identified as probable the loss of their jobs after completing their maternity leave. A symbiotic relationship was identified between these effects and the salary level of the participating women.

Gender equality can increase economic efficiency and improve other development outcomes such as removing barriers that prevent women from having the same access as men to education, economic opportunities, and productive inputs, which in turn can lead to widespread productivity increases that are all the more important in an increasingly competitive and globalized world (World Bank, 2011). In short, although not all actions imply a significant change, especially because there are aspects that are rooted in Colombian culture, this can lead to social and labor changes generating very significant contributions to Colombian society and the large population of economically active women of reproductive age in the country.

Acknowledgment

Abstract

Research motivation: Limited financial resources allocated for hospitalized older patients represent a significant economic problem both on public health systems and their families. This study addresses an empirical gap in the literature concerning the determinants of hospital costs in the group of older patients using the SHARE database. **Methodology:** Socio-demographic and clinical variables as the possible factors that may influence the hospital high cost were considered. The analysis included 9,671 patients, who were hospitalized in 2015. **Main findings:** On the studied population, 873 patients were identified as CO (cost outliers). The highest share of CO was in Switzerland (12,65%) and the lowest in Italy (5,80%). We found that individuals permanently sick or disabled, who suffered from cancer, diabetes, heart attack or chronic lung disease were associated with being hospital cost outliers. Individuals who reported difficulties with walking 100 m are more often cost outliers. The risk of being a cost outlier increased by 20% with each day spend in hospital. We did not find age and gender to be associated with being high cost outliers. **Implications:** Action is needed to improve the efficiency of hospitals and community services and improve the coordination of care, especially for older people with comorbidities. A clear understanding of the drivers of high inpatient costs of older patients is essential for developing and implementing policies aimed at improving the efficiency of public expenditure. Interventions aimed at promoting disease prevention and physical activity are also needed.

Keywords: Hospital Costs, Cost Outliers, Older People, Inpatient Costs.

Introduction

The substantial increases in healthcare costs over recent years are associated with a rapid increases in the older age population, greater longevity and the illness burden of older patients who represent the fastest-growing age group in the majority of the developed countries (Mody *et al.*, 2008). Throughout the developed European countries, life expectancy, together with the share of older people in society is continuously increasing. The reason for this can be attributed to the success of both preventive and curative medicine, combined with widespread technological advances, and declining fertility rates (Lehnert *et al.*, 2011). It is widely known that older people generally use more health services than other age groups, that they are at higher risk of more expensive long-term institutional care, and that they consume majority of health care expenditure. An aging population, together with the increasing cost of medical technologies, has been indicated as a major cause of the increase in healthcare expenditures and place a particular burden on hospital medical services. It was observed that average per-capita total health care expenditure is higher for older patients, mainly due to inpatient hospital-related spending. Older patients represent a large number of hospital admissions, consuming a substantial share of hospital resources. They will often increase the demand for acute beds and have a prolonged hospital stay (Liotta *et al.*, 2012). Limited financial resources allocated for hospitalized older patients represent a significant economic problem both on public health systems and their families. A high proportion of hospital costs incurred at the end of life is associated with the management of terminal illness (Round *et al.*, 2015) and the type of care received at these time (Sato and Fushimi, 2009).

Hospital services are the most expensive component of health systems and hospital inpatient care represents the largest single component of healthcare expenditures (Hay, 2014). Hospital costs have been subject to many studies

and traditionally used as a surrogate to evaluate healthcare efficiency, as well as hospital resource utilization. A better understanding of cost outliers is essential to the improvement of management and financing of hospitals, as well as the whole health care system. An outlier is defined as data object that does not comply with the general behaviour of data, very different and inconsistent with the remaining data (Freitas *et al.*, 2012). It can be a result of an error or the natural variability of data. The high cost outliers are of great interest to hospital managers who have a goal to reduce the cost of hospital stays using a rational management strategy and to find clinical justification for funding these outliers on the basis of their real costs in order to moderate the consequences of a case mix financing system (Pirson, 2006). According to a study conducted in Spanish hospitals cost outliers account for almost 18% of hospital costs (Cots *et al.*, 2000). A knowledge of cost outliers is also important for the protection of more expensive patients and for the appropriate financing treatment of uncommon cases (Lee *et al.*, 1998). In an era of increasing budget restrictions, economic analysis of cost outliers and an identification of the factors affecting high health costs outliers could help define a strategy to reduce costs or use existing resources more efficiently.

Information on the determinants of hospital expenditures amongst older people is one of the most important issues in health policy. Despite the financial burden, research on the factors that impact hospital high cost outliers of an aging population is scarce. This study addresses an empirical gap in the literature concerning the determinants of hospital costs outliers in older patients using SHARE database. The identification of factors associated with cost outliers among aging adults may result in the development of effective interventions for healthcare policy across Europe. The strength of our analyses is the use of a large and representative dataset in Europe. We believe this is the first study to examine the impact factors of the hospital cost outliers among older people.

Methods

Sample and Data

We used cross-sectional data from the 6th wave (2015) of the Survey of Health, Aging and Retirement in Europe (SHARE) (Börsch-Supan, 2019). It is a multidisciplinary, cross-national micro data base containing information on health, social networks and socioeconomic status of over 60,000 Continental Europeans, aged 50+, from the following countries: Austria, Belgium, Czech Republic, Denmark, Estonia, France, Germany, Greece, Italy, Luxembourg, Poland Portugal, Slovenia, Spain, Sweden, Switzerland. We examined data relating to individuals who were hospitalized in 2015.

Variables

We considered socio-demographic and clinical variables as the possible factors that may influence the hospital high cost outliers. Socio-demographic variables included gender, age and job situation. Clinical variables covered length of stay per hospitalization (LOS), number of nights spent in hospital in 2015 as well as health risk factors, health status and functional ability. Health risk factors included BMI, high blood cholesterol, hypertension, physical activity and previous heart attack. Functional ability factors considered physical and mental condition including difficulties with walking 100 m and memory abilities. Health status factors regarded number of chronic diseases and the medical diagnoses and comorbidities, such as stroke, cerebral vascular disease, cancer, chronic lung disease, diabetes and high blood sugar.

Hospital costs outliers

We calculated the individuals' costs of hospitalization by multiplying total number of nights spent in hospital in 2015 for each patient with average inpatient cost per day for the country. The inpatient cost per day was calculated by dividing hospital expenditure (inpatient curative and rehabilitative care costs in 2015) in evaluated countries by number of inpatient curative bed-days in each country based on information from OECD database. All costs in current prices were converted to Euro on the basis of exchange rate provided by SHARE database.

Statistical Analysis

To select the outliers, we used the interquartile method using the median and the interquartile distance (Stanisz, 2007). The high outliers were identified as the 75th percentile + 1.5*interquartile range. To identify the low cost outliers, we used the corresponding rule: 25th percentile – 1.5* interquartile range. Because the rule 25th percentile – 1.5* interquartile range detected a negative trim-point in further analysis, we considered only high cost outliers. The analysis of contingency tables was executed with the Pearson's $\chi 2$-test. Continuous variables without normal distribution were analysed with the Mann-Whitney test. Univariate and multivariable logistic regression analysis

were used to determine the determinants of CO. A p-value of 0.005 was considered significant. Statistical analysis was carried out using StatSoft Statistica software version 13.3.

Results

The analysis included 9,671 patients, who were hospitalized in 2015. The patients included in the analysis were more likely to be retired (67.9%). Majority of them were female (53.9%). The average age was 58 years. Overall average LOS was 7.23 days. The average number of chronic diseases per patient was 2.65. The most frequently found chronic diseases (hypertension) affected more than 50.5% of patients, followed by diabetes (20.1%) and chronic lung disease (12.3%). 25% of patients had difficulty walking 100 metres and 23% of patients had suffered from a heart attack.

On the studied population, 873 patients were identified as cost outliers (tab. 1). The highest share of CO was in Switzerland (12.7%) and the lowest in Italy (5.8%). The highest treatment costs of CO were in Switzerland (9,652.30 €/person) and the lowest in Estonia (1,758.92 €/person). In Portugal the hospitalization costs of CO were more than 14 times higher than CI and it was the highest difference among studied countries. In Greece this difference was the lowest (6 times).

Table 1: Hospital cost outliers (CO) and inliers (CI) by country

Country	CI n=8800	CO n=873	CI n=8800	CO n=873	p-Value
	n (%)		Inpatient costs median [Q1-Q3] [€/person]

n (%), number and percentage, Q1, first quartile, Q3, third quartile

The difference for LOS and number of nights spent in hospital between CI and CO was statistically significant for all analysed countries (tab. 2). The mean LOS per hospitalization for cost outliers was 28.77 nights and was almost

6 times higher than in case of CI. CO spent on average 58.59 nights in hospital in 2015 and it was 8 times more days than in case of CI. In most of the evaluated countries CO differed from CI by physical activity (Austria, Belgium, Czech Republic, Denmark, Estonia, France, Germany, Greece, Luxembourg, Poland, Slovenia, Sweden, Switzerland,) health condition, measured by number of chronic diseases (Austria, Belgium, Czech Republic, Germany, Denmark, France, Italy, Slovenia, Switzerland) and reporting difficulties with walking 100 m (Czech Republic, Estonia, Slovenia, Spain, Greece, Italy, France, Germany, Switzerland, Sweden, Luxembourg, Denmark, Belgium, Austria). In most of the countries extreme high costs of hospital treatment was observed in case of patients reporting cancer (Austria, Czech Republic, Germany, Denmark, Spain, Greece, Italy, Poland, Sweden).

Table 2: Characteristics of cost outliers (CO) and inliers (CI) by variables

We analysed all countries together by using univariate and multivariate linear regression model. All independent variables that were proved significant in the univariate analysis were included in the multivariate model (tab.3). We found that individuals permanently sick or disabled (OR = 1.654, [95% CI, 1.173-2.330]), who suffered from cancer (OR = 2.869 [95% CI, 2.232-3.688]), diabetes (OR = 1.353, [95% CI, 1.062-1.724]), heart attack (OR = 1.261, [95% CI, 1.003-1.586]) or chronic lung disease (OR = 1.540, [95% CI, 1.276-1.859]) were associated with being hospital cost outliers. Also, individuals who reported difficulties with walking 100 m (OR = 1.771, [95% CI, 1.433-2.190]) are more often cost outliers. Moreover, the risk of being cost outlier increase of 20% with each day spend in hospital (OR = 1,219, [95% CI, 1.205-1.234]).

Table 3: Multivariate analysis of factors associated with cost outliers

Explanatory variables	β-coefficient	Adjusted		
		OR	(95% CI)	p-Value
LOS [days]	0.198	1.219	(1.205-1.234)	<0.001
Employed or self-employed	-0.688	0.502	(0.313-0.806)	0.004
Permanently sick or disabled	0.503	1.654	(1.173-2.330)	0.004

Discussion

Social and clinical factors were statistically significant predictors of health cost in many other studies, but they were not analysed using large international data of aging population. There is a lack of population-based empirical studies on the complex relationships between high hospital costs outliers, socio-demographic characteristics and health status of the senior. Our study is the first using SHARE database that presents significant new data from a comprehensive healthcare perspective on the complex association between the hospital cost outliers and their potential determinants, in a very under-researched and rapidly growing group of elderly in Europe.. We found that one of the most important determinant of hospital cost outliers of older people is disability (permanently sick or disabled, with difficulties with walking 100 m.). The conclusion that functional disabilities are strong determinant of health cost among older people was confirmed by Wagner *et al.* (2006), who found that Functional Independence Measure (FIM) scores were significantly associated with health costs. They explained that FIM affects discharge costs mostly through its association with LOS. They also found strong relationship between LOS and inpatient rehabilitation costs. According to them LOS explained approximately 80% of the variance in cost of inpatient specialized rehabilitation stays because such costs are fixed or recurring. Also the study conducted on the patients

with stroke showed that the patients with greater disabilities at discharge and longer LOS are more likely to face higher costs of medical care (Wei *et al.*, 2010).

Our study revealed the relationship between the cost outliers and the number and kind of chronic diseases and impairments. Our findings are confirmed by Lenhert *et al.* (2011) based on 35 studies concerning relationship between multiply chronic diseases and health expenditure for aging populations, found a positive association between multiply chronic diseases and health expenditure. They noticed that health expenditure significantly increased with each additional chronic disease and several of them observed a curvilinear (near exponential) relationship, in which expenditure roughly doubled with each additional chronic disease (Schneider *et al.*, 2009; Wolff *et al.*, 2002). Generally, the more diseases a patient had, the higher the costs of an additional disease. According to our analysis the older people with health problems such as heart attack, diabetes, chronic lung disease or cancer generate the highest costs in the hospitals. According to an American study two thirds of older Medicare beneficiaries had 2 or more types of chronic conditions and accounted for 99% of health expenditures, but the reason for such situation is a higher risk of hospital complications that increase the costs (Lochner *et al.*, 2011). The study regarding older patients with pneumonia showed that neither the patient's age nor comorbidities were independently associated with high costs if they had no associated complications (Cases *et al.*, 2008). Likewise Kaplan *et al.* (2002) also found patients with complications require longer hospital stays, resulting in increased costs. The other authors found that complications increase the costs up to six times, due to the need for more tests and treatments especially, due to the extension of the LOS (Cases *et al.*, 2008). Older people with multiply chronic conditions are high users of hospital care; in particular emergency department services mainly because of higher LOS caused by high rates of hospital admissions for adverse events (Shah *et al.*, 2001).

Similar to other studies, we did not find age and gender to be associated with being high cost outliers (Wei *et al.*, 2010). On the other hand, some other researchers reported that women were more likely to face higher costs than men (Evers *et al.*, 2002). Our findings suggest that, although women had a higher level of use of health services, they accounted for less of the hospital expenditure. This may be because women are more health conscious than men and take better care of themselves (Dean, 1989). Furthermore, they visit physicians more often than men, which results in earlier detection of health problems (Cockerham, 1998).

A clear understanding of the drivers of high inpatient costs of older patients is essential for developing and implementing policies having an aim to improve the efficiency of public spending (Alhashmi and Campus, 2008). Our study showed that such factors as disability, comorbidities and high LOS can contribute to an important portion of hospital costs and therefore should be considered by hospital managers and health policy makers. We presume that the individuals reported as high cost outliers are significantly less active because they are permanently sick or disabled, have problems with walking, suffered from heart attack, have more chronic diseases, like cancer, diabetes, chronic lung diseases. It is because of these problems they are more often admitted to hospitals and spend more time there.

In conclusion, we suggest that reductions in hospital costs could result from effective policies that enable them to introduce new models of care to reduce LOS. Given the projected rapid aging of the population, efforts to improve the efficiency of hospitals and community services and improving the coordination of care especially for disable patients with comorbidities are needed. Integration between inpatient, outpatient and social care could result in global economic savings for the public health system and could be clinically advantageous for the patients. We advocate for interventions aimed at promoting disease prevention and physical activity.

Key points

- Rates of hospital cost outliers among older people varied from 5.80 to 12.65% across Europe.
- Factors associated with extreme high inpatient costs include the length of stay in hospital, poor health and comorbidities.
- Older people reporting heart attack, diabetes, chronic lung disease or cancer are more often cost outliers.
- Interventions aimed at promoting disease prevention and physical activity among older people are strongly needed.

Cross-Functional Integration and The Success of Servitization Production of Manufacturers - Examination of The Necessary Conditions

Mirosław MATUSEK

Silesian University of Technology, Zabrze, Poland
mmatusek@polsl.pl

Abstract

The aim of the article was to examine the level of necessity of the condition of inter-functional integration in the organization to achieve different levels of revenues from the sale of services of production enterprises depending on the type of service orientation of the product offer (i.e. product support services (SSP) and customer support services (SSC). Servicing is now becoming an important factor contributing to the competitiveness of producers. This phenomenon, understood as the adoption of a service-oriented business strategy, in line with the theory of organizational fit, requires changes, e.g., in the organizational structure. Producers may separate an autonomous service unit or strive to integrate a service organization with a product. There are arguments for one or the other in the results of empirical research and in theory. Unfortunately, the results currently achieved show a contradiction. On the basis of a survey conducted on a sample of 186 manufacturers, the necessary conditions were tested using one of the non-parametric methods, i.e., Necessary Condition Analysis (NCA). The study showed that cross-functional cooperation determines the achievement of different levels of revenues from the provision of product and service solutions. This condition severely limits the revenues generated when the manufacturer provides the SSC category offer.

Keywords: Servitization, Service Orientation, Industry 4.0, Organizational Ties, Necessary Condition Analysis (NCA).

Introduction

In the last decade, manufacturing companies have experienced many transformations that radically change the concepts of building a competitive advantage, relationships with customers, suppliers or ways of developing, producing and delivering a product offer (Gersch and Goeke, 2007). Currently, the two observed macro-trends, i.e., the phenomenon of servitization and the Industry 4.0 initiative, are perceived as particular challenges faced by manufacturing companies.

Servitization is a phenomenon (process) observed at the level of national economies and at the level of manufacturers themselves. At the manufacture level, servitization is manifested by the gradual integration of the product offer with the service component (Raddats et al., 2019). Other authors define the phenomenon of servitization as an innovative way of organizing capabilities and processes in order to better create common (customer and supplier/s) value by moving from selling products to providing integrated solutions consisting of products, services and knowledge (Kowalkowski et al., 2017; Martinez et al., 2017; Szmal, 2015) Such a transformation is rooted in the value architecture of the solutions offered to customers, composed of the mechanisms of creating value, its delivery, capturing and their complementarity (Teece, 2010). Industry 4.0, in turn, is considered to be a new industrial development scenario with the convergence of various new technologies supported by the Internet of Things (IoT). (Reischauer, 2018)

These issues have long been treated as separate research areas, the first of which focuses on customer value, and the second on the value of internal business processes (Coreynen et al., 2017). In fact, both trends are closely related and their common ground are digital technologies on which, in turn, are based intelligent products, digital services, mass personalization of the product offer or other innovative value proposition models (e.g., Coreynen et al., 2017). Technologies and solutions that make up Industry 4.0, such as IoT, Big Data, Cloud computing, analytics or cybersecurity, are currently becoming the basis of an increasingly complex and integrated product and service offer. (Frank et al., 2019) Product and service solutions (PSS) are defined differently (e.g., Kowalkowski et al., 2017).

Cite this Article as: Mirosław MATUSEK "Cross-Functional Integration and The Success of Servitization Production of Manufacturers - Examination of The Necessary Conditions" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

The article assumes that the PSS is an individualized offer responding to the (complex) needs of service users (clients), which is designed and delivered interactively with the recipient and whose components offer synergistic added value by combining products and/or services so that its value is something more than the sum of the offered value of its individual components. PSSs integrate components such as product, service and knowledge into unique combinations to meet customer requirements and needs. In extreme cases, the inputs incurred by the supplier are compensated by the recipient on the basis of value in use.

The development and delivery of services or product-service solutions are more complex tasks than the production of products, although as such they may not be perceived in this way (at least initially) by managers of manufacturing companies. Alghisi and Saccani (2015) found that the development of advanced services without properly aligning the internal components of an organization (e.g., service orientation of the strategy and portfolio of a service-oriented product offer) with external aspects (customers and other participants in the service delivery network) may prove very difficult. The development of production companies by increasing the role of services in their product offer creates huge (new, unknown to production companies) strategic, operational and financial risks. Although recent quantitative research (e.g., Böhm et al., 2017) indicate that services can have a positive impact on the results of manufacturing companies, however, according to the concept of organizational adjustment (Mintzberg, 1993), it depends on factors inside the organization and in its environment. This article focuses on the match between the service offer and organizational relations. Gremyr et al. (2014) indicate in their research that manufacturing companies that start developing new business focused on services experience an imbalance between strategy and practice or everyday activities undertaken in the enterprise. Authors (e.g., Gebauer, 2008; Raddats et al., 2019) quite commonly agree that the sources of this mismatch should first of all be seen in the inconsistency between the adopted business strategy (here expressed through the product and service offer) and the service-oriented organizational structure.

Although researchers generally agree that inter-functional and inter-organizational cooperation are important aspects of the integration of services and products in the form of product-service solutions, knowing whether these factors are necessary conditions at the same level with a different degree of product offer orientation service has so far not been explored. Moreover, most of the research on the preconditions for the success of servitization, except for a few cases, e.g., Antioco et al. (2006), was exploratory, qualitative research based on case studies. (Raddats et al., 2019)

Hence, the presented research results try to answer the question whether, and if so, how the organizational ties determine the levels of revenue from the sale of product and service solutions achieved by manufacturing companies, depending on their type?

Data analysis was performed using the Necessary Condition Analysis (NCA) tool (Dul, 2016). The next part of the article presents the state of knowledge on the impact of the criteria of internal structuring of an organization and organizational cooperation depending on the type of product offer orientation towards services (SSP, SSC). Then the research method, the course of the research and their results are presented. The article ends with conclusions indicating future research directions.

Research Review

The type of product offer orientation towards services and the internal structuring of the organization

In research on the conditions for the success of servitization of production companies, one of the most frequently mentioned factors is the organizational structure oriented at providing integrated product and service solutions. (Fliess et al., 2017; Raddats et al., 2019) The organizational structure is, along with people, technology and goals, one of the elements of the organizational system. Its essence lies in the appropriate combination of the goals and tasks of the organization, resulting from the strategy and technology of executive processes, with people and the ways of influencing them in the work process. (Chandler, 1962) It defines the arrangement of the company's elements and the relations between them. The way of dividing work into different tasks, i.e., integration and/or separation of tasks and responsibilities, is reflected in the organizational distinctiveness of activities related to the offered products and services. The distinctiveness of these activities represents the degree to which tasks and responsibilities related to service activities are integrated as a separate unit in the organizational structure or strategic business unit. (Oliva et al., 2012). A production company adopting a service orientation changes its product offer towards an increase in the share of services or integrated product-service solutions. Thus, the level of

diversification of the organization's businesses increases. It is one of the factors influencing the greater degree of organizational structure (by creating divisions, facilities). Therefore, it can be assumed that with the increase in the level of service orientation, with the increase in the maturity of the servitization of production manufacturers, they will try to separate units responsible for the development and provision of services from those responsible for the delivery of products.

Indeed, some authors (e.g., Gebauer, 2008) indicates that the organizational distinctiveness of the service business is positively related to the service orientation of manufacturing enterprises. The authors argue that manufacturing companies, which from the beginning of their activity based their business model on the sale of products, while integrating tasks related to services in the same organizational unit, are not able to focus sufficiently on services or understand their unique requirements. (Gebauer et al., 2009, p. 109) According to the authors, the integration of tasks related to products and services in one organizational structure is proof that managers do not notice the fundamental differences between the business of products and services. This is conducive to a low level of service orientation in organizational structures, which in turn leads to the achievement of unsatisfactory results related to the sale of the service offer. The separation of a unit responsible for the service business supports the service orientation of the enterprise and helps to avoid the service paradox. (Matusek et al., 2018) The separation of the service unit allows for fully autonomous management of customer relations, developing the service offer, setting its price and choosing the methods of providing services (Auguste et al., 2006; Gebauer, 2008). The separation of a service organization emphasizes the strategic involvement of a manufacturing company in service activities (e.g., Gebauer et al., 2009), moreover, as shown by the authors (Oliva et al., 2012), an independent service unit in the organizational structure positively influences the results achieved by the enterprise on the sale of services.

On the other hand, Neu (2005) posits quite the opposite. According to the author, the creation of an autonomous service unit in the organizational structure limits the development of service activities. Consequently, the separation of the service unit may limit the benefits achieved by the enterprise. The reason for this in marketing is explained by the increase in the moments (points) of contact with the client, which can harm the relationship with them. Thus, the separation of a service unit in a manufacturing company can significantly increase the coordination efforts between the company and customers (Raja et al., 2018). Separating product and service activities can lead to internal conflicts. In addition, unbundling of service activities create a risk to product activities, which means that companies face internal resistance from product activities, and managers have to deal with conflicts at the interface between service and product activities (Gebauer et al., 2009). In their subsequent studies, Neu and Brown (2008) confirm that in the case of integration of a service unit with a product unit, it is possible to obtain a synergy effect in the form of product and service solutions and improvement of knowledge transfer in the process of developing and delivering such solutions.

With such contradictions, research was conducted on the impact of the separation of an autonomous service unit on the achieved results depending on the service orientation of the product offer (on the type of services in the product offer). The services are not homogeneous and the authors classify them according to various criteria. (more e.g., in: Raddats et al., 2019) However, the most frequently used classification of services in servitization research is that proposed by Mathieu (2001). The author divides the services into those that ensure the proper functioning of the product (SSP) (related to the delivered product, e.g., service activities) and those that support the customer's activities (SSC) (e.g. consulting, services aimed at improving business or operational processes at the customer). The product offer, which consists of services supporting the customer's activities, is characterized by a greater degree of service orientation. Antioco et al., 2008) Fliess et al. (2017) argue that the more service-oriented the product offer, the more appropriate a structure with a separate service unit. Kowalkowski et al., (2017), Gebauer et al. (2009) and Oliva et al. (2012), on the contrary, state that an autonomous organizational unit is appropriate with a low level of service orientation in the product offer. In turn, in the aforementioned works by Neu (2005) or Neu and Brown (2008), the authors conducted research on a sample of manufacturing companies with a product offer characterized by a high level of service orientation, such as SSC (their product offer was dominated by services supporting customer activities). The authors confirmed the correctness of the integration of organizational units responsible for the development and delivery of products and services.

Type of product offer orientation towards services and organizational ties

Organizational structure is not only a way to integrate or divide tasks, but it is also an element that determines cooperation inside and outside the organization. Hence, the problem of distinguishing a service unit in the organizational structure of production companies entering the path of servitization is related to the discussion on the impact of inter-functional and inter-organizational cooperation on the service orientation of enterprises. (Raddats et al., 2019; Gebauer, et al. 2009) Organizational ties are relations of interdependence, having the nature of

interactions of material and information resources within the enterprise (Swink et al., 2015). Inter-organizational ties are similarly defined as such interactions between organizations in which information, material or energy exchange takes place. The parties to the inter-organizational exchange (here, the production company and end customers and/or intermediate customers) must show mutual commitment. This research was limited to presenting the results of research on organizational constraints.

While there is widespread agreement among researchers about the positive impact of both collaboration between departments (e.g., Edvardsson et al. 2014) or between organizations (Edvardsson et al. 2014) on the results achieved by enterprises or competitive advantage, the authors also try to define the necessary conditions for achieving such results. It is similar among authors who study the phenomenon of servitization (e.g. Fliess et al., 2017; Gebauer et al. 2009; Antioco et al., 2008), who include the criterion of distinguishing basic organizational units or the orientation of the product offer towards services. Fliess et al. (2017) based on the literature review, hypothesise that regardless of whether the service activity is integrated or separated from the product activity, the factors contributing to the success of servitization are the exchange of information within the company and between customers. At the same time, the authors assume that the effect will be greater with a greater degree of service-oriented product offer. In the case of having a product offer characterized by a high degree of service orientation, producers are forced to integrate such organizational units. Neu and Brown (2008) At the same time, they must support collaboration within the company in order to meet customer requirements effectively and efficiently. Storbacka (2011, p. 709) states that integrated product-service solutions with a high level of service orientation are inherently cross-functional. Antioco et al. (2006) examined the relationship between the relationship of cooperation within the company and the service orientation of the product offer. The authors, as few in their research, took into account the heterogeneity of services, i.e., two categories of product and service offer were distinguished. The first category of the product offer (less service-oriented) in which services that ensure the proper functioning of the product dominate, and the second (highly service-oriented) in which services supporting the activities and business processes of customers dominate. The results of the research showed that there is no direct relationship between inter-functional cooperation and the types of service orientation of the product offer. However, the authors noticed that the relationship between services supporting the customer's activities (an offer with a higher degree of service orientation) and the achieved sales volume of products becomes stronger with the increase in inter-functional cooperation.

Summing up, it can be concluded that researchers disagree as to whether (and if so, under what conditions) the integration or separation of service activities from product-related activities contributes to the success of the servitization of producers. Secondly, there is generally agreement that inter-functional and inter-organizational cooperation are important aspects of integrating services and products in the form of an integrated product-service offering. However, our knowledge of whether these factors are necessary conditions at the same level with varying degrees of service orientation in the product offering has not yet been explored. Thirdly, in research on the conditions necessary for the success of servitization, apart from a few cases, e.g., Antioco et al. (2006), there is a lack of studies that would prove the truth of the hypotheses made by statistical generalization on a larger sample than a few examined cases. Most of the research conducted in this topic was exploratory, qualitative, based on case studies. (Raddats et al., 2019)

Research Method

NCA Method

In order to find out about the conditions necessary for the production companies to achieve a given level of revenues from the sale of product and service solutions, which may be 1. the separation or integration of organizational units responsible for providing the product and service component of the product offer, 2. interfunctional ties, the NCA method was used (Dul, 2016). The method belongs to the group of non-parametric methods which use the linear programming procedure, but the influence of the random factor on the features of the objects is not taken into account. The advantage of NCA resulting from the non-parametric nature of the method is that it does not require the presentation of a functional relationship between the analyzed variables. The NCA helps researchers determine the necessary level of condition necessary (but not sufficient) to achieve the desired level of effect (outcome). In that case, it allows you to answer, among others, the question of the type "what minimum level of the value of the independent variable X is necessary for a given level of the value of the dependent variable Y (understood as the desired result, effect, result)?". In order to identify the necessary value of a given variable for the desired effect to occur, in the NCA method, the so-called ceiling line. In the Cartesian coordinate system, the ceiling line is the boundary line separating the zone without registered observations (points) from the zone in which these observations are located. The ceiling line takes the form of a non-decreasing (linear) function with intervals (Dul, 2016). There are many ways to determine such a line. The NCA adapted, inter alia, solutions from the

previously developed method of boundary data analysis (Data Envelopment Analysis - DEA) and free envelope determination methods (Free Disposal Hull - FDH). (Dul, 2016) The "empty" zone (usually above the ceiling line) is proof of the existence of a necessary condition. It will vary in size, thus determining the measure of the necessity effect (d), but not the sufficiency condition. In NCA, the magnitude of the precondition effect is expressed as the size of the zone above the ceiling line ("empty" zone) to the entire area of recorded observations. (Dul, 2016) The effect is stronger with increasing the zone above the ceiling line. As with other measures of effect size, such as the correlation coefficient r, in NCA the value of the necessary condition effect ranges from 0 to 1. (Dul, 2016)

Measures

The constructs used in the study were generated using the positions of the scales already used in previous studies. In order to measure the service orientation of the product offer, the aforementioned classification of services according to Mathieu (2001) was used, thus dividing the product offer into one in which services that ensure the proper functioning of the product (SSP) dominate and one in which services supporting business activities and processes of clients dominate (SSC). The respondents indicated from the presented list of services which type of services the company has in its product offer. The list of SSP (n = 11) and SSC (n = 8) services was taken from previous research (Eggert et al., 2015). For each of the 19 services presented, the variable was dichotomous (0 = "we do not offer", 1 = "we offer"). As the number of services was different for each of the two groups, the obtained values were normalized. Depending on which standardized SSP or SSC value was higher, it was assumed that the manufacturer has a product offer more oriented towards SSP or SSC, respectively. On this basis, enterprises were divided into two groups, which were the basis for the search for necessary conditions depending on the type of services offered. The first group (SSP) included 112, and the second group (SSC) 72 enterprises.

Based on a proposal by Antioco et al. (2008) the results achieved by enterprises were obtained from the respondents by declaring the percentage share of the revenues obtained from the sale of services in the total revenues from sales. A subjective measure is used here because, as stated by Homburg et al. (2002), in the case of an integrated product and service offer, an objective measure, e.g., in terms of amount, is in many cases very difficult (if not impossible) to obtain. This situation takes place mainly when the enterprise has not separated an organizational unit with assigned full responsibility for the costs and profits incurred from service activities. (Gebauer et al., 2009)

Organizational cooperation was operationalized on the basis of Storback (2011) and Langerak et al. (2004). Ultimately, the respondents rated the 4 statements relating to the interactions of teams of employees participating in service-related tasks (service development, marketing, sales of services) with other functions in the company (product development, production, marketing). The scale consisted of the following items: 1. employees of individual organizational units (departments) coordinate their activities related to the services provided to our clients; 2. individual organizational units (departments) jointly meet the needs of customers; 3. individual organizational units (departments) are jointly responsible for relations with customers; 4. employees of various organizational units (departments) jointly participate in working visits to clients; 5. employees of various organizational units (departments) jointly make decisions that affect customer relations. The rating was made on a 5-point Likert scale from 1 "disagree" to 5 "completely agree" and 3 "neither agree nor disagree"). In order to determine the reliability of the scale, the Cronbach's a-coefficient was used, i.e. a measure determining the consistency of items present in a given scale (in other words stating to what extent the questions included in a given factor determine the same theoretical construct). The obtained value of the Cronbach's a-coefficient at the level of 0.69 was achieved after removing statement No. 5. With a cut-off value of 0.6 on a 5-point Likert scale (Hair et al., 2006), the final 4-item measurement tool has sufficient reliability to measure inter-functional relationships.

Research sample and data collection method

The surveyed entities were production companies based in Poland, which declared to have services in their product offer, and employing at least 10 employees. The research sample was selected on purpose based on the Central Statistical Office data from the REGON register, 2017. Moreover, the selection of enterprises was based on a quota, trying to comply with the data of the Central Statistical Office in such dimensions as the percentage share of enterprises from a given section and division of the Polish Classification of Activities and according to the employment structure. To collect the data, the CATI method of direct interview (computer-assisted telephone interview) was used. The interviews were conducted by one of the largest companies in Poland conducting this type of research. Ultimately, the research sample consisted of 320 companies. The respondents were employees of higher and middle management level, i.e. owners, presidents, managing directors, sales and marketing directors, service department managers and new product development managers. The respondents represented companies from seven different industries: production of machinery and equipment (41%), production of electrical equipment (16%), activities related to software and IT consultancy and related activities (13%), production of motor vehicles,

trailers and semi-trailers trailers (10%), manufacture of other transport equipment (9%), manufacture of computers (8%), telecommunications (3%). The surveyed companies employed: 10-49 employees (51%), 50-249 employees (41%), 250 employees and more (9%).

Results from the NCA analysis

The research included determining the ceiling line for the necessary condition of inter-functional cooperation (*IntraFirm*) depending on the type of service orientation of the product offer (i.e. *SSP* and *SSC*) (Fig. 1). Of the two implemented methods of determining the ceiling line, i.e. CE-FDH and CR-FDH, with discrete data, a better line fit is obtained by the CE-FDH method. (Dul, 2016) Secondly, the necessary conditions effect sizes were determined (Table 1). Based on experience (Dul, 2016, p. 271), the effect is assessed as "medium" when the value is between 0.1 and 0.3, above 0.3 to 0.5 as "large" and above 0.5 as "very large". Third, a table of the degree of limitation of the achieved effect levels (*UPU*) by the type of offer (*SSP* and *SSC*) was generated (Table 2).

Table 1: The results of the analysis of the necessary conditions: values of the effects *d*

Dimension/value of the effect of the necessary condition *d* (Method of determining the ceiling line)	$d_{(CE_FDH)}$	$d_{(CR_FDH)}$
IntraFirm (SSP)	0.266	0.206
IntraFirm (SSC)	0.525	0.350

Source: own elaboration

Table 2: Table of constraints: required minimum levels of a precondition for the various desired performance levels (broken down by type of service offer)

UPU %	0	10	20	30	40	50	60	70	80	90	100
IntraFirm (SSP)	NN	NN	NN	2.20	9.90	17.70	25.50	33.30	41.00	48.80	56.60
IntraFirm (SSC)	5.00	11.00	17.00	23.00	29.00	35.00	41.00	47.00	53.00	59.00	65.00

Source: own elaboration NN - condition is not necessary

Fig.1 : Ceiling (limit) lines for the necessary condition of cross-functional cooperation -"IntraFirm" depending on the type of product offer service orientation (*SSP* and *SSC*). *UPU* - achieved level of the share of revenues from sales of services

The obtained results of the necessity effects (*d*) (Table 1) by the CE-FDH method (as mentioned above, providing a better fit for discrete variables), indicate that both in the case of the product offer dominated by *SSP* services and in the case of *SSC*, the values of the necessary condition of inter-functional cooperation (*IntraFirm*) between product and service functions are greater than zero($d_{(CE_FDH)} > 0$). The value of $d_{(CE_FDH)}$ is smaller for *IntraFirm* (*SSP*) where $d_{(CE_FDH)}$= 0.266 (average effect according to the adopted scale) than for *IntraFirm* (*SSC*) where $d_{(CE_FDH)}$ = 0.525 (very large effect). This means that the inter-functional ties between tasks related to products and services are a necessary condition for achieving specific revenues from the sale of services, both in the case of the offer of services aimed at the proper functioning of the product (SSP) and directed at the client's business and operational processes (*SSC*). However, the effect (*d*) is stronger for *SCC*. Thus, it means that organizational ties strongly limit revenues from the sale of *SSC*. Additional knowledge is provided by the table of constraints (Table 2) built on the basis of the designated ceiling line. (Dul, 2016) The values of the dependent variable (here the share of *UPU* sales

revenues) are expressed as a percentage of the range of (observed) values (0% = lowest observed value, 100% is the highest observed, 50% is in the middle of the lowest and highest observed value). The lowest observed value of *UPU* was "up to 10% share of revenues from sales of services in total revenues from sales". The highest observed value was the achievement of "over 80%" of revenues from sales of services. The remaining lines are the corresponding values of the independent variables according to the ceiling (also expressed as a percentage of the range). On this basis, the results from Table 2 indicate that in the case of an SSC-oriented product offer, the necessary condition for achieving "up to 10%" of revenues from sales of services is to have a bond between product and service functions at the level of 5% (of course, the scale adopted in the research). In the case of a product offer dominated by SSP services, cross-functional ties become a necessary condition in order to achieve a level of revenues from services higher than 20%.

Conclusion

The aim of the research was to identify the necessary conditions for generating revenues from the sale of services by manufacturing companies entering the path of servitization. Two conditions were examined, i.e. the separation of a service organizational unit and inter-functional cooperation with various types of the adopted orientation of the product offer towards services. The Necessary Condition Analysis (NCA) method was used to identify the necessary conditions.

The obtained research results showed that the revenues from the sale of services are not conditioned by the criterion of internal structuring of the organization. In the studied sample, both enterprises that distinguished organizational units on the basis of the similarity of activities and tasks (units responsible for the product and services) and with the object-oriented criterion, where the basis for structuring is the similarity of a specific business object (integration of product and service activities) achieved good and bad results from the sale of services. (Table 1) Such a result was obtained in both of the analysed groups of services offered. This means that there is no optimal organization design for producers following different servitization trajectories. Producers have to adapt the project to the adopted service strategy, and this with the rapid development of new technologies (including those that make up Industry 4.0) changes with the increasing "maturity" of producers' servitization.

The second conclusion that can be drawn from the conducted research concerns the role of organizational ties in the development and delivery of services 1. accompanying the products sold (SSP) and 2. the customer's business and operational processes (SSC). Organizational ties are a necessary condition for the achieved sales revenues, both in the first and the second category of services. The table of constraints (Table 2), additionally showed that inter-functional ties limit the revenues from the sale of services to a greater extent when SSC services dominate the enterprise. This means that companies that extend their offer with more complex services (SSC services are considered such), wishing to achieve greater revenues from the sale of services, should pay special attention to the development of organizational ties. SSC services are oriented towards the client's processes, and cross-functional collaboration allows for a more "holistic" approach to meeting their needs. This "holistic approach" is a cross-functional commitment to specific activities that include finance, manufacturing, delivery, development of personalized product and service solutions, and customer service.

This research, like others, has its limitations. The method that was used is relatively new and despite its wider use, it is still being developed as a research tool. Furthermore, the NCA method is complementary to, rather than competitive, to traditional quantitative methods. Therefore, the collected data in subsequent stages of the research will also be analysed using more scientifically established statistical methods in order to compare the achieved results. It will also allow, in addition to confirming/negating the results obtained here, for another verification of the reliability of the NCA method.

In the research, revenues from sales, subjectively indicated by the respondents, were used as a measure of the servitization effect. In subsequent studies, it is proposed to adopt more objective measures and other dimensions of the effects of servitization, e.g. the competitive advantage achieved.

Edvardsson et al. (2014) indicate that inter-organizational cooperation may have a positive impact on the internal coordination of development activities and the provision of product and service solutions. Therefore, in the future, it is also interesting to examine the necessary level of organizational ties in achieving specific results by manufacturing companies, broken down by type of product and service solutions provided.

Corporate Resultative Innovativeness Assessment On the Example of Polish IT Companies

Tomasz L. NAWROCKI

Silesian University of Technology, Faculty of Organization and Management, Zabrze, Poland,
E-mail address: tomasz.nawrocki@polsl.pl

Abstract

The paper aims to present an empirical application of an originally developed solution for corporate resultative innovativeness assessment and comparison. The proposed solution provides a framework for resultative innovativeness assessment of enterprises based on the methodology used in multivariate comparative analysis. Within the proposed method of assessing corporate resultative innovativeness, the focus is on its general qualitative dimension as defined in the Oslo manual and it is assumed that the individual assessment criteria are based on generally available data published by enterprises in their periodic reports (mainly annual, due to greater completeness of data and verification by external auditors). In this context, selected companies from the information technology sector listed on the Warsaw Stock Exchange were examined. The need for corporate innovativeness measurement and evaluation for management purposes arises from its growing importance in building enterprise value and achieving long-term competitive advantage. The proposed solution enables a fairly current and good orientation in the area of the results of innovation activity carried out by the assessed enterprises. This can be the basis for various comparison analysis and managerial decisions regarding e.g. innovation management as well as managing corporate image and reputation.

Keywords: Corporate Innovativeness, Results of Innovation Activity, Innovativeness Assessment, Multivariate Comparative Analysis.

Introduction

In the literature, innovation and innovativeness have been for many years seen as the driving forces of economic development, which was first pointed out by Joseph A. Schumpeter in his vision of creative destruction referring to the mechanism of changes in a capitalist economy (Schumpeter 1950). Although the theory of innovation proposed by Schumpeter refers to the economy in the first half of the 20th century, the importance of this phenomenon has not devalued over time, but on the contrary, it has become one of the main determinants of competitiveness (Prahalad and Hamel 1990; Drucker 1992; Porter 1998), revenue growth (Patterson 1998) and organizational survival (Hurley and Hult 1998).

At the same time, despite the great interest of the scientific community in innovation and the innovativeness phenomenon over the years, it is hard to talk about some generally accepted definitions. Understanding innovativeness, as well as innovation itself, has been considered by particular researchers in many different contexts. The term innovation is on the one hand related only to significantly changed or new solutions (OECD and European Communities 2018), and on the other, identified with all changes recognized by people as a novelty in relation to the previous state (Kotler 1994). Innovations are also considered in terms of the subject – as a result (here there is an additional distinction between product, process, marketing and organizational innovations), or in functional terms – as a process (Goldsmith and Foxall 2003).

A similar diversification of perception concerns the issue of corporate innovativeness. Most often it is emphasized that innovativeness is a specific ability or skill of an enterprise to search for, implement and disseminate innovations continuously (Pomykalski 2001). Consequently, possessing it allows the enterprise to implement new products, processes, or ideas (Hult et al. 2004). More extended definitions depict innovativeness as an organization's inclination to seek, create, and implement new products, technologies, services, markets, and management methods; to undertake actions in uncertain situations; to monitor the market and competition, forecast market situations and react quickly to changes by breaking routines, changing ways of communicating, and developing new ways of organizing (Francik 2003). It should also be noted that many definitions of innovativeness

go beyond merely exposing the same abilities or skills, emphasizing the results of its possession and use. In this way, innovativeness is the ability of an organization to control and maintain high dynamics of value creation, which manifests itself in using the occasion to generate change and to process, as well as implement, new ideas in practice (Jin et al. 2004) earlier than other enterprises (Rogers 1995). Innovativeness as an ability should also enable the effective allocation of resources, aiming at creating the optimal configuration of competitive advantage (Morgan and Berthon 2008).

Therefore, innovativeness can be seen in the context of the widely understood potential for creating innovation and continuous engagement in its development, the so-called potential innovativeness or innovative potential as well as innovation capabilities, and in the context of specific effects of undertaken innovative activities as well as their impact on the enterprise's financial results – the so-called resultative innovativeness (Nawrocki 2012; Yeung et al. 2007). Differentiation between these two types of organizational innovativeness is very important, as high innovative potential does not necessarily translate into high results of innovative activity (Simpson et al. 2006) which, among others, refers to the issue of innovation management.

The pressure on innovation and innovativeness in recent years is particularly strong and visible in a variety of contexts. It can be said that everyone wants to be perceived as 'innovative'. Unfortunately, due to the width and complexity, and therefore ambiguity, of the innovation and innovativeness concept, in recent years it can be seen that different entities, especially companies, very easily identify themselves as innovative. The reasons for such actions arise from the fact that innovativeness, regardless of the documented positive impact on the development of economies or corporate results, is associated with a certain prestige and inspires respect, which even with very limited, or even pretended, innovative activities can easily be used in marketing operations. Therefore, particular importance should be given to the quick and possible objective assessment of corporate innovativeness, which should allow for their reliable differentiation. Such an assessment could also be useful in the intercompany innovation management process, as well as its image and reputation management (Szwajca 2014).

In the literature we can find various approaches to the corporate innovativeness measurement, which can be gathered in several groups. The first one consists of methods used by different international and national institutions (e.g. Eurostat) to investigate periodic innovative phenomena: the Frascati Manual – recommendations regarding the evaluation of companies' engagement in research and development (OECD 2015), and the Oslo Manual – recommendations regarding collecting and analysing data in reference to widely understood innovative activity (OECD/Eurostat 2005 and 2018). The second group involves methods based on the resource approach, which includes the concept of strategic management with the focus on investigating an organization's resources and skills (e.g. Shum & Lin 2010). The third group consists of methods focusing on the time factor, specifically emphasizing the moment of implementing an innovation in relation to the competition – historical, cross-sectional and complex methods (e.g. Rogers 1995). Clearly, apart from the abovementioned methods, there are many others that can be traced in the literature, but they are merely some modifications or compilations of them.

However, at the same time, it is quite often stated that most of the innovation and innovativeness studies are generally quite radically affected by various kinds of drawbacks such as: very narrow perception of innovativeness, problematic data updating, lack of synthetic innovativeness measure/assessment or generalization of final results (e.g. Lev 2001; Mazzucato 2006). Therefore, to fill the gap in this area, the author conducts research on developing a corporate innovativeness assessment model based on publicly available sources of data. The aim of this paper is to present a practical application of the designed so far version of the model focused on corporate resultative innovativeness based on the example of selected IT companies – IT systems – listed on the Warsaw Stock Exchange (WSE). Proposed model provides comprehensive understanding of enterprise's innovative activity results, and subsequently enables conducting more in-depth research, in particular comparative analysis on corporate innovativeness and its management.

Possibilities in the area of resultative corporate innovativeness assessment

From the viewpoint of the newest version of Oslo methodology (4th edition), which is generally accepted basis for research on innovation activity of enterprises, the assessment of innovative activities results/outcomes focuses on two basic dimensions (OECD/Eurostat 2018):\

- qualitative measures, that are grouped by areas of influence:
  - markets (e.g.: upgrade goods or services, expand the range of goods and services, create new markets, increase the reputation, brand awareness, or visibility of goods and services),

  - production and delivery (e.g.: upgrade outdated process technology or methods, improve quality of goods and services, improve flexibility for producing goods and services, increase speed of producing goods or delivering services, reduce labour, material or energy costs),
  - firm organisation (e.g.: improve capabilities for absorbing, processing and analysing knowledge, improve sharing or transfer of knowledge with other organisations, improve the efficiency of function of the firm's value chain and communication within the firm, improve working conditions, health or safety of the firm's personnel, implement a new business model),
  - environment and society (e.g.: reduce negative environmental impacts/deliver environmental benefits, improve public health, safety or security, improve quality of life or well-being).
- quantitative measures, that concentrates mainly on:

  - product innovations (e.g.: number of introduced innovations during the observation period, share of sales accounted for by product innovations),
  - business process innovations (e.g.: the percentage of a firm's personnel who were directly affected by business process innovations during the observations across an organisation, the change in sales that can be attributed to business process innovation).

Moreover, in the initial versions of the Oslo manual (OECD/Eurostat/European Union 1997), in the context of assessing the results of innovative activities of enterprises, attention was also paid to:

- impact of company's innovation activity on its financial performance (e.g.: sales revenue growth rate, operating margin growth rate).
- evaluation of introduced innovations from the viewpoint of their general and specific characteristics e.g.: level of novelty, complexity, diffusion capabilities, quality, usefulness, … – LBIO Methodology.

In addition to the abovementioned Oslo methodology, authors of numerous studies on corporate innovativeness or innovation activity also point to other possible criteria for evaluation its results:

- patents or patent applications (Jung et al. 2008),
- patent citations (Makri and Scandura 2010),
- ratio of sales of new products to R&D expenditures (Gumusluoglu and Ilsev 2009).

As it can be seen, the current research in the area of measuring the results of innovative activity of enterprises provides a wide range of criteria for assessing this phenomenon. At the same time, the question arises as to how such an assessment should be carried out, which generally relate to the issue of collecting adequately detailed, complete and comparable data. Taking into account the high popularity of the issue of innovativeness nowadays (everyone wants to be perceived as innovative) and disclosure of information in this area, two possibilities can be distinguished here:

- assessment based on data collected through a questionnaire survey addressed to the assessed enterprises (Survey Data Approach – SDA),
- assessment based on publicly available data, in particular those disclosed by enterprises in periodic reports and corporate websites (Public Data Approach – PDA).

Obviously each of mentioned approaches has its advantages and disadvantages. In the case of the first one, the assessment is based admittedly on a much more detailed and complete data, that are consistent with the guidelines of the Oslo methodology, but also there is no guarantee of their credibility and receiving (the two main threats associated with data collection through surveys), and carrying out regular assessments is much more burdensome than in the second approach. It should be also noted, that in the Oslo manual itself it is pointed out that in statistical surveys on innovation it is difficult to ask respondents to provide detailed quantitative measures, especially those relating to the impact of innovation, even only to a very close approximation, because making appropriate calculations often requires extensive analysis (OECD/Eurostat 2018).

On the other hand, in the case of the second approach, the undoubted advantages are the velocity, ease of performing the assessment (assuming data availability there is no need to develop and conduct a survey research) and its repeatability, but the crucial disadvantage – dependence on the quality of information policy in enterprises in the field of innovation, which in mostly cases translates into an approximate nature of received assessments, arising from gaps and shortcomings in disclosed by companies' public information (Nawrocki and Żabka 2011).

From the presented list of advantages and disadvantages of both approaches to the resultative innovativeness assessment, it can be concluded that due to the large variety of the information policy of enterprises in the field of innovativeness, the approach based on public data practically has no sense in scientific research. Indeed, due to the difficulties in accessing detailed and comparable data on innovations implemented and disseminated by enterprises, in relation to quantitative data such a statement may be considered true. At the same time, however, taking into account the translation of innovative solutions into the results and economic performance of enterprises, indicated in the Oslo manual (OECD/Eurostat 2018) and confirmed in numerous studies (e.g.: Laursen and Salter 2006, Camisón and Villar-López 2014, Chae et al. 2018, Jin and Choi 2019), the approach based on public data can be applied in relation to the assessment of result-oriented innovativeness in the overall qualitative dimension. In this case, as the basic criteria for assessing corporate resultative innovativeness can be used in particular: sales growth rate in a given period, market share, productivity of assets, work efficiency and business profitability.

Obviously, the scope of resultative corporate innovativeness assessment, limited to the abovementioned issues, is not complete in the understanding of the Oslo manual, but taking into account the credibility of the financial data that constitute the basis for such an assessment, as well as easy access to them and their repeatability (periodic financial statements), the obtained assessment nevertheless has significant cognitive value. It is also worth noting here that although the information about the number of innovations implemented or disseminated by the enterprise, including their characteristics, is important, its actual innovativeness, including the efficiency of innovative activity, is mainly determined by economic and broadly understand market. Only the acceptance of new solutions by the market and the community gives the company a chance to return outlays on innovative activities, improve its results and competitive position. Without this acceptance and the subsequent dissemination of innovative solutions, even the most technologically advanced innovations may turn out to be misfires, which, instead of improving, will cause a deterioration of the company's competitiveness and its financial results, and ultimately even threatening its market existence

Research Methodology

Within the proposed method of assessing corporate resultative innovativeness, the focus is on its general qualitative dimension as defined in the Oslo manual and it is assumed that the individual assessment criteria are based on generally available data published by enterprises in their periodic reports (mainly annual, due to greater completeness of data and verification by external auditors). It should be noted that, on the one hand, the adopted assumptions make the final grades received comprehensive, and on the other, they enable easy generation and updating of these assessments. By comparing the key issues proposed in the literature in the context of the impact of implemented and disseminated innovations on enterprises business and the informative value of periodic reports published by them, the proposed partial evaluation criteria along with the assumptions relating to them are listed below:

- Sales Growth Rate in 3 years period, which informs about changes in the company's sales over a period of 3 years (it is assumed that a shorter period of the indicator might not be sufficient for the effect of the innovative solutions implemented and popularized by the company to be fully revealed):

$$Sales\ Growth\ Rate\ in\ 3\ years\ period = \left(\frac{Sales\ Revenues\ in\ the\ year\ t}{Sales\ Revenues\ in\ the\ year\ t-3} - 1\right) \cdot 100\% \qquad (1)$$

- Market Share, which informs about the share of a single company in the total sales of the sector; due to the difficult access to information on full sales in a given sector, it is assumed that the indicator is calculated on the basis of the total sales revenues of the assessed entities from a given sector:

$$Market\ Share\ = \frac{Sales\ Revenues\ of\ the\ j-th\ enterprise}{Sales\ Revenues\ of\ all\ investigated\ enterprises\ from\ j=1\ to\ n} \cdot 100\% \qquad (2)$$

- Productivity of Assets, which, by indicating how much sales revenues fall per unit of capital engaged in assets, informs about the efficiency of using them by the company:

$$Productivity\ of\ Assets = \frac{Sales\ Revenues}{Average\ Assets\ Level} \qquad (3)$$

- Work Efficiency, which, by indicating how much sales revenues fall per one employee, informs about the efficiency of the workforce involved in the enterprise:

$$Work\ Efficiency = \frac{Sales\ Revenues}{Average\ Number\ of\ Employees} \tag{4}$$

- Gross margin on sales, which, indicating how much profit / loss falls per unit of sales revenue after deducting own costs, informs about the profitability of the company's core business:

$$Gross\ Margin\ on\ Sales\ = \frac{Gross\ Profit\ on\ Sales}{Sales\ Revenues} \cdot 100\% \tag{5}$$

- Net margin on sales, which, by indicating how much profit / loss is attributable to a unit of sales revenue after deducting own costs increased by selling and general administrative costs, informs about the profitability of the company's operating activity, excluding other net operating costs, which are often burdened with the results of one-off events (e.g. impairment losses on assets , profit / loss from the sale of assets, creation and release of reserves):

$$Net\ Margin\ on\ Sales\ = \frac{Net\ Profit\ on\ Sales}{Sales\ Revenues} \cdot 100\% \tag{6}$$

It should be noted that all the assessment criteria listed above are stimulant (the higher the value, the better). However, their connection with activities related to specific types of innovation (product, process, organizational and marketing) is difficult due to the interpenetration and overlapping of the impact of various innovative solutions, as well as the occurrence of certain synergies between them (product with marketing innovations and process with organizational innovations), then taking into account the list of factors relating to different objectives and effects for all four types of innovation presented in the third version of the Oslo manual (OECD/Eurostat, 2005), it can be concluded that the first two assessment criteria concern the impact of more product and marketing innovations and the other four impact more process and organizational innovations.

The final synthetic assessment of the resultative corporate innovativeness of a given entity in the proposed solution is assumed to be obtained as a result of the implementation of subsequent steps in accordance with the diagram presented in the Fig. 1 – generally a typical one for solutions based on the methods of multivariate comparative analysis.

Fig. 1: Diagram of the process of obtaining a synthetic resultative innovativeness of a given enterprise

Source: Own work.

First, it is assumed that, within the adopted time series, the partial evaluation criteria will be calculated on the basis of data from periodic financial statements. In the case of a quarterly time series, the data for calculations should be transformed to the annual form due to elimination the influence of seasonality on the values of individual indicators.

Then, in order to reduce the possible impact on the indicated criteria of evaluation of factors other than innovative activity (e.g.: changes in exchange rates, prices of commodities, materials and energy, as well as wages and employee benefits, merger and acquisition operations), their values were averaged for a period of 4 years.

Subsequently, due to the fact that the separated partial criteria differ in terms of measurement units and ranges of values, for the purpose of their unification and at the same time facilitating the calculation of the overall resultative corporate innovativeness assessment, their normalization should be performed. In this context, as well as in terms of calculating the synthetic measure, it was decided to apply the methodology proposed by D. Strahl (1978). Thus, out of many different methods, normalization was selected using the quotient transformation formula, based on the maximum value of individual variables in a given research period:

$$z_{tj} = \frac{x_{tj}}{\max\limits_{t} x_{tj}}, \quad \max_{t} x_{tj} \neq 0 \tag{7}$$

where:

x_{tj} – value of the *j*-th evaluation criterion in the *t*-th research period,
z_{tj} – normalized value of the *j*-th evaluation criterion in the *t*-th research period (from 0 to 1).

In the case of criteria with negative values, due to their unambiguously negative meaning and the lack of significance in the scale of "negativity", it was decided to adopt their normalized value at the level of zero. On the other hand, in order to avoid distortion caused by too high readings of the individual partial criteria values, it was decided to establish their highest reference level (max x_{tj}) based on the upper limit of the typical range of variation:

$$\max_{t} x_{tj} = \bar{x}_j + s, \tag{8}$$

where:

$\bar{x}_j$ – average value of the *j*-th evaluation criterion from the point of view of all analyzed entities and the entire research period,
s – standard deviation of the *j*-th evaluation criterion from the point of view of all analyzed entities and the entire research period.

Finally, in accordance with the methodology of D. Strahl, the formula of the arithmetic mean of normalized partial measures z_{tj} was adopted as the basis for the calculation of final resultative corporate innovativeness assessment:

$$MS_t = \frac{1}{K}\sum_{j=1}^{K} z_{tj}, \tag{9}$$

where:

MS_t – a synthetic measure of resultative corporate innovativeness assessment in the *t*-th research period.

The indicated structure of the synthetic measure assumes the equal weight of individual evaluation criteria and the range of the adopted values from 0 to 1. Values closer to 0 meana low level of resultative corporate innovativeness, and values closer to 1 a high one.

Research Results

The practical application of the proposed method of resultative corporate innovativeness assessment was carried out on the example of eight IT companies listed on the Warsaw Stock Exchange (WSE), listed as part of the IT sector (IT systems, No. 822): Asseco Poland, Atende, Comarch, Quantum Software (Quantum), Sygnity, Talex, Unima 2000 Teleinformatics Systems (Unima) and Wasko.

The calculations were made on the basis of the annual reports for the years 2011-2019 published by the aforementioned companies. In the case of Talex, these were individual reports, and for other entities, due to the fact that they operate as capital groups, consolidated reports.

Following the diagram presented earlier (Fig. 1), the relevant data was first collected, and then, on their basis, the partial criteria for the resultative corporate innovativeness assessment in the years 2011–2019 were calculated (formulas 1-6). Subsequently, this way obtained time series of annual variables was recalculated using a 4-period arithmetic average, shortening its scope to years 2014-2019, and then normalized (formulas 7 and 8) and the final

assessments of the resultative corporate innovativeness of the studied entities were calculated (formula 9). The values of partial evaluation criteria for investigated enterprises expressed as 4-year averages, their averages and the values of max x_{tj} needed to their normalization, are presented in the Fig. 2-7, and final assessments of resultative innovativeness for investigated enterprises in the research period in the Fig. 8.

Fig. 8: The values of partial criteria and final resultative innovativeness assessment for investigated enterprises in the research period from 2014 to 2019

Source: Own calculations based on annual reports of investigated enterprises.

Taking into account the obtained results, it can be concluded that in terms of resultative innovativeness the clear leader among the studied IT entities is Asseco Poland, with the highest assessments in each year of research period at stable level about 0.8. Taking into account the partial evaluation criteria of Asseco Poland, it can be concluded that this company has generally no weaknesses. It is distinguished by high ratings for Market Share and Net Profit on Sales. In addition, it is characterized by relatively high ratings for Sales Growth and Gross Profit on Sales (here recently systematically decreasing) and above average Work Efficiency (here – systematic improvement). Asseco is the worst in terms of Productivity of Assets, but at the same time it should be noted that this is an average rating, not a low one.

Subsequently, in terms of the assessments of resultative innovativeness, one can point to Atende, Comrach and Quantum, for which the latest assessment readings are between the levels of 0.6 and 0.7. These entities in some respects lag behind Asseco Poland (especially Market Share and Sales Growth), but at the same time they can also boast high readings in terms of certain partial evaluation criteria. In the case of Atende, these are Work Efficiency and Gross Profit on Sales, in the case of Comarch – Gross and Net Profit on Sales, and in the case of Quantum – Gross Profit on Sales and Productivity of Assets.

Among the remaining entities, only in relation to the Unima company we can talk about the resultative innovativeness at an above average level – readings at the level between 0.5 and 0.6. Sygnity, Talex and Wasko have recently recorded readings clearly below the average level of 0.5, the worst of which is the first one of them.

Summary

Proposed model of resultative corporate innovativeness assessment, whose practical application has been shown in this paper using the example of eight IT companies listed on WSE, can be an interesting alternative or a complement to the so far commonly used methods that are mostly based on survey research. One of its biggest advantages is the possibility of obtaining one final resultative innovativeness assessment with the use of data from public sources, which additionally are periodic. This enables the fairly current and good orientation in both the general and more in-depth resultative innovativeness level of the assessed enterprises, which can be the basis for various comparison analysis and managerial decisions regarding e.g. innovation management, as well as managing corporate image and reputation.

Although the presented solution requires further refinement taking into account the ongoing changes in the increasing information openness of enterprises, in particular in the field of non-financial information (Vukić et al. 2017), it should be noted that there are great opportunities ahead of it both in the development dimension as well as the practical application for scientific and managerial purposes.

Abstract

The regions constantly look for optimum forms of innovation development. However, current experience show the problem in the flow of knowledge. The aforementioned observations are the basis for the review of the technological observatories network partners activity within the area of materials production and processing within the Silesian Province. More and more efficient solutions are searched for thus the paper is related to the functional and attribute review of the competence centre (including living lab) in the area of materials production and processing. The objective of the paper is the analysis of the competence centre functioning as a solution supporting the technological development process within the area of materials production and processing. The developed case study confronts the actual operations of the engaged entities with these necessary for the competence centre functioning. The study analyses the offer and activity of the companies engaged in running a technological observatory according to the situation at the end of 2019. The process continuously evolves and improves the technological observatory members offer. However, the analysis of current state has disclosed some gaps representing the space to overcome along the path to full development of a competence centre. The performed analyses and studies were used to review the readiness for implementation of the innovation management model using the Competence Centre concept in the technological area of materials production and processing. It seems possible within the 2 - 3 year-long time perspective while standing up to the challenge of filling the competence gaps and assuming self-funding of own operations. The method this will be performed is the key. Cooperation competences are necessary: relation and network competences with consideration of their basic components and outlining the network approach assumptions provides the space for effective operations.

Keywords: Competence Centre, Innovative Operations, Innovation Conditions.

Introduction

At the age of knowledge-based economy, building a competitive economy is difficult to imagine without involving scientific achievements perceived as the sources of new knowledge into this process. At the same time, proper innovative processes management within the European regions is recognized as the key element for good standing of the European economy in the world. Innovative processes are affected first and foremost by the regional innovation strategies. Thus, the regional innovation system providing rational flow of network in the region is a critical challenge. Innovativeness depends on relationships of entities generating knowledge and these absorbing it. The process is still far from optimum therefore the need to search for more efficient solutions. Basically, the regional innovation system is created by two main types of actors and relations between them. The first one is companies that consume innovations and finally develop value. The other is organizations creating the innovativeness infrastructure that supports innovative processes in the region due the possessed key competences. Current experience show the problems in the flow of knowledge despite the emergence of knowledge intermediaries. The above observations were the basis to review the forms of cooperation in favour of innovations within the scope of innovation ecosystem in the Silesian Province. The Network of Observatories MATERIALS also looks for new efficient forms of cooperation between entities operating within the area of materials production and processing (Knop L., Olko S., 2018).. Thus, the paper relates to the functional and attribute review of the competence centre (including living lab) in the area of materials

production and processing. The objective of the paper is the analysis of the competence centre functioning as a solution that should support the technological development process within the area of materials production and processing.

Literature Review – Competence Centre, Living Lab – Functional and Attribute Characteristic.

The competence centre term is commonly used in European countries. This state is the first indicator of an effectiveness of this tool of supporting the pro-innovative activities. International acclaim results from relatively low sensitivity to the legal, economic, or cultural context. This concept is heavily used for the development of clusters, but it also has entered the world of corporations that create their own competence centres to support their business entities. Despite the presence of the competence centre concept in the instrumentation of innovation support tools, these are not the beings of standard functionality, attributes, role, or organisation and management form. Their compliance with the needs of specific economic industry or region decides about their effectiveness. The adaptation imperative is justified by four most common roles of the competence centres, that is: training, technology transfer, research and development, and increasing the competitiveness of enterprises. Potential benefits of coordinated activity of a community of specialised enterprises consist of achieving the synergy, thanks to, among others:

- development of the participants' competences (specialisation)
- strengthening the complementarity of these competences (co-specialisation)
- fostering a long-term advantage over non-network entities.

Studies on management agree that the basic component of competences are the processes of creating a value, that is what the enterprise implements in order to provide their clients the value expected by them (Matusek, Wolny, 2018).. The second component of the competences are the skills, both on the individual and collective level. The third component of the competences consists of the resources allocated to the processes of creating value and to the skills, since it is not possible to implement them without an adequate material, financial, or human resources (Fig.1). (Czakon, 2008)

Fig. 1: Semantic elements of the enterprise competences

Source: W. Czakon, Istota i przejawy kompetencji relacyjnej, [In] Zarządzanie strategiczne w badaniach teoretycznych i w praktyce, A. Kaleta, K. Moszkowicz (red), Prace Naukowe Uniwersytetu we Wrocławiu nr 20, 2008, p. 58

Therefore, the competences lead toward the configuration of knowledge, processes and resources into a possibly effective totality that can emerge within the limits of a single enterprise and can lead to the creation of closely related strategic network. In case of potential competence centre in the field of production and material processing, both of the dimensions may have a significant meaning.

In the management studies, the competence term is present since 1971, when K. Andrews has defined it as "what the organisation does particularly well". Defining the competences is focused on (Ray, Ramakrishnan, 2006):

- Knowledge - where the competence means „*collective learning of an organisation, particularly how to coordinate various production skills and integrate various technology trends*“,
- Resources - definition of the competence as „*an ability to sustain a coordinated exploitation of the resources in order to achieve the goals of the company* “,

- Complexity - where the competence is „*a set of skills, complementary resources and organisational routines that together allow the organisation to coordinate a specific set of activities in a way that leads to achieving the competitive advantage on specific markets*".

As stated in the strategic goal 2.1 of the current Regional Innovation Strategy of the Silesian Province, for the years 2013-2020 (RIS 2013), an establishment of key competence centres was assumed, such as:

- science and research competence centres (SRCC),
- functional and operational competence centres (FOCC).

SRCC is defined as an organisational entity, or the network of entities (universities, science entities etc.) that consists of the scientists, analysts, field experts, who by becoming the key link between the science, business and local government authorities, will be responsible for performing such tasks as: the world trends analysis in terms of implemented specialisations, preparation of the innovative projects, obtaining and developing competences, searching for talents in the studied fields; coordination of the key projects.

FOCC are the organisational entities, or the networks of entities (such as, among others, science, technological parks, transfer centres) that bring together the field specialists responsible for implementation and coordination of the innovative projects, performed for the development of smart markets. The feature of these centres is focusing on: commercialisation of technology, financing innovation, supporting cross-linking activities, observation and analysis of the smart market development in specialisations.

It was assumed that the centres have a high level of autonomy in defining their own strategies and activities, however, the level of supporting their activities will depend on the influence on the region's development. Development of a demand-driven strategy, that is the strategy of making a better use of the research results, is expected from the centres. As the global examples show, the main goals of the competence centres include:
for the SRCC:

- increasing the ability of enterprises to implement innovations through financing the research conducted in close cooperation between the companies conducting the research and established research groups
- conducting the research in order to increase the attractiveness of the region as a place oriented on smart markets
- supporting the research clusters (knowledge clusters) that are at the forefront of international research for the development of smart markets
- strengthening the education of scientists in the fields important for the development of smart markets

for the FOCC:

- supporting the commercialisation processes and innovation implementation processes by enterprises and networks of enterprises
- supporting the development of cooperation networks and technology clusters developed in the field of smart markets

Performing the overview of the competence centre term, it is necessary to pay attention to the Living Lab concept that is considered as a new model of introducing innovations and means interdisciplinary approach to the creation of innovations, in which the user of innovative solutions constitutes the main reference point. In the Regional Innovation Strategy of the Silesian Province, the following definition was adopted: Living lab is a laboratory which main task is to make available the space and resources for the research organised by enterprises (in B2B model), or by enterprises with participation of the users (in B2C model) (RIS, 2013). There is a rapid increase in the awareness of the role of consumers in the value creation processes. The benefits resulting from the demand-driven approach to the innovations are increasingly noticed. Thus, the User-Driven Innovation concept becomes an important method of implementing the innovation. Engagement of the users of innovative products or services may appear on various stages (Wojnicka) :

- joint creation, that is collaborative designing by the users and producers;
- exploration, that is finding emerging applications, behaviours and market opportunities;
- experimenting, that is implementing living scenarios among the users community;
- evaluation, that is assessing the concept, products and services in accordance with socio-ergonomic, socio-cognitive and socio-economic criteria.

The literature describes living lab as a user-centric research methodology for creating, prototyping, and refining complex solutions in multiple and evolving real life contexts (Eriksson, Niitamo, Kulkki, 2005). In the literature, we also find attempts to define this term while referring to the systemic approach to innovations, as well as directly to

creating and testing the technology. The first of these approaches (Feurstein, Hesmer, Hribernik, Schumacher, 2008) describes living lab as a systemic approach to the innovation in which the stakeholders, all the most important participants of creating the value of products or services, are the direct participants of the development process. The second optics defines living lab (Ballon, Pierson, Delaere, 2005) as an experimental environment where technology is created and tested in everyday life conditions, while the users testing new solutions are being their co-creators. Living labs can be understood as both the environment and the method of implementing and developing innovation. Three approaches to the living lab concept are functioning in the subject literature, treating them as (Macełko, Mendel) :

1. methodology of conducting research and implementation activities in the reality of economy based on the knowledge and information society; new ideas are developed and tested in real conditions and their users/consumers may participate at all stages of creating the new product (lgd-tur_org_pl),
2. environment - a place where innovations (of various kind) are created, where needs of the users are the most important criterion. Such process of creating innovations is characterised by openness - open innovation and democratic nature,
3. merging the two concepts.

A.Stahlbröst presented the most important goals of the living lab activity that consist of (Stahlbröst, 2008):

1. inciting and stimulating cooperation and European innovativeness in the research activity and local and regional development,
2. making it easier for the users to participate in innovation development processes,
3. focusing the innovation development processes on social perspective, not only the technological one,
4. participation of the users in innovation development processes at all their stages, not only at certain times, who continuously make attempts and express their opinions.

Referring to such defined competence centre term, including living lab, it is worth to take a look at the knowledge intermediary term, which in the subjective aspect and in the material activity will remain in certain complementarity with the competence centres concept. However, wanting to answer the question of who can be considered a knowledge intermediary, the conclusions made on the basis of the analyses conducted on the basis of various cognitive perspectives should be examined. It can be noticed that this subject is covered by two traditions in the literature, the sociological one and the one related to managing the technology that, despite being characterised by similarity of the research questions, were developing with relatively little interaction between them (Fleming, Waguespack, 2007). On the one hand, it is possible to point to Burt and his theory of structural gaps that shows the intermediary as an entity connecting directly unrelated actors, but in such way that the intermediary can use his/her position, for example, to obtain further promotions faster. On the other hand, Allen and Tushman described how the intermediary, often on a managerial position (boundary spanner), contributes to obtaining the best results of the entity by identifying, performing translations and forwarding information inside and between the companies. Therefore, we have two distinct pictures of the intermediary, that is, on the one hand, a broker as calculating and political operator, and on the other hand, a boundary spanner as respected attendant that directs important information inside and outside the organisation. In the regional system, the translation of these relationships can be found in Kauffeld-Monz and Fritsch (Kauffeld-Monz, Fritsch, 2013) that have studied the brokers of regional innovation system in terms of their concentration on social benefits (knowledge passed on to others) and private benefits (knowledge received from others). By systematic review of the literature, Long, Cunningham and Braithwaite (Long, Cunningham, Braithwaite, 2013) have distinguished several types of the intermediaries that differ on the basis of characteristic features and factors deciding about their motivation. Therefore, it can be said that an intermediary is:

a. broker - acts as an intermediary between unrelated actors/clusters, aims to make some transactions easier, resolve the conflict, but also to increase personal power or social capital; loyalty to the two groups can be problematic,

b. consultant/cosmopolitan/itinerant broker - connects two unrelated actors in external cluster/clusters, trying to make the negotiations between them easier, but also to use their lack of relation,

c. coordinator - connects directly unrelated entities inside of their cluster, aiming to improve the coordination efforts, or to centralise the knowledge exchange,

d. liaison - connects two unrelated groupings without taking any particular approach to either of them, i.e. by helping in negotiations in commercial transaction,

e. representative, connects the gap between the actor of the same grouping with the actor from a different grouping, so as to make the external contact easier,

f. gatekeeper - connects the grouping to which he belongs to with the other one, thus controlling the incoming and outgoing information, often negatively connected with the phenomenon of keeping the information, or positively as the one bringing useful information or filtering the useless ones,

g. go-between - occurs between two unrelated actors offering certain services, i.e. facilitating an access to advice, resources; in case of too much information flow, it can become a bottleneck,

h. information/knowledge broker - keeps two unrelated groups informed and makes them coordinate actions with each other, its action prevents fragmentation;

i. peripheral specialist, holder of specialised knowledge that shows tendencies to occupy a peripheral position, so as to take care of his specialisation on the one hand, and be available for consultations on the other,

j. mediator/conflict resolver that tries to increase an understanding between the two sides separated by different expectations in the field of knowledge, is often well-versed in two sides;

k. tertius gaudens and/or tertius iungens, which will be discussed later in the study.

In the Silesian province, the configuration of actors of the innovation ecosystem of the Silesian province was adopted, as presented in RIS, among which the authors of the research (Szmal, Janiszewski, 2018) identified the activities of knowledge intermediaries in the regional innovation system. This approach could be useful in defining the activities of knowledge intermediaries of the competence centres in the field of production and material processing.

Materials and Methods

Competence centre within the area of materials production and processing in the Silesian Province - case study

The paper is a result of the research procedure based on the review of scientific literature concerning management and the case study of a consortium established to implement the project "Network of Regional Specialist Observatories in the Entrepreneurial Process of Discovery" (NO RIS in EPD). The case study makes a review of the technological observatory operational situation in the area of materials production and processing in the Silesian Province. It confronts the actual processes taking place in the case in question with the competence centre functioning requirements. The study analyses the offer and activity of the companies engaged in running a technological observatory according to the situation at the end of 2019. The content related scope of the area MATERIALS PRODUCTION AND PROCESSING has been defined in the "Program for Technology Development of the Silesian Province within 2019 - 2030". It covers the following issues:

- metallic materials
- polymer materials
- ceramic materials

To complement information on the research environment, it should be emphasized that the Project "Network of Regional Specialist Observatories in the Entrepreneurial Process of Discovery" (NO RIS in PED) lasted from January 2017 to March 2019 and was co-funded from the European Regional Development Fund. Project value: 4 756 146.11 PLN including the leader and project partners' own resources. The objective of the project was the support and enhancement of the regional development management within the scope of the regional scientific and technological potential and the increase of number of Specialist Observatories according to technological areas indicated in PTD as well as R&D sector entities and companies. Moreover, the objective of the project was to disseminate efficient business models among companies, disseminate specialist reports developed by technological observatories concerning available technologies and R&D&I cooperation options. The project was mostly directed to companies to increase their knowledge on technologies and market trends which would allow to take actions in order to raise competitiveness and innovativeness both at the regional and national level, through adapting the support tools at the regional level (PED) (Janik A., Ryszko A., Szafraniec M. 2018).

The study itself performed for the needs of this paper is related to a consortium established for the purposes of implementation of the technological observatory in the area of materials production and processing in the Silesian Province. The consortium composition: Silesian University of Technology, Organization and Management Faculty and Non-Ferrous Metals Institute. The objective of the observatory within the technological area of Materials Production and Processing was ongoing monitoring of development of the technologies applied in the Silesian Province economy sectors, related to materials production and processing: metallic polymer, ceramic and composite.

The basic activities of the model competence centres include:

1. Operations within the scope of pro-innovative services, especially:

    1.1. Technology watch in the area of materials production and processing,
    1.2. Intellectual property protection strategies,

1.3. Support within the scope of technology transfer and commercialization,
1.4. Creating and testing business models for start-up projects,
1.5. Professional ideas incubating centre,
1.6. Business advisory, appraisal of technology and support during contact with VC.

Competences of this type serve the following role: training, knowledge dissemination and innovativeness support.

2. Operations within research and development scope, i.e.:

   2.1. Formulating research challenges that correspond with market and technological trends within the area of materials production and processing,
   2.2. Creating research consortia in the area of materials production and processing,
   2.3. Analyses in favour of the emerging sectors and horizontal relations,
   2.4. Good practices base,
   2.5. Technological road maps.

3. Activities within the scope of training and communication, i.e.:

   3.1. Organization of conferences, seminars and workshops on the subject,
   3.2. Analyses of the needs and personnel competences development options, including managerial personnel in the area of materials production and processing,
   3.3. Organization of training and post-graduate studies within the scope of technology, internationalization and intellectual property, etc.
   3.4. Active participation in key assemblies that shape the development conditions in the area of materials production and processing,
   3.5. Development of inter-organizational communication system, using modern information tools.

4. Activities within the scope of internationalization;
   4.1. Building a relationship capital to international scale,
   4.2. Searching for partnerships, preparing and coordinating regional, national and international projects,
   4.3. Organization of study trips,
   4.4. Good practices base,
   4.5. Support for networking activities.

Hereinbelow, the authors made an attempt to analyse and then to evaluate how the activities of the consortium members fill the activities of the model competence centre with contents in the area of materials production and processing.
Results of the review are presented in table 1.

Table 1: Comparison of basic activities of the model competence centre with the activities of entities implementing the technology observatory in the area of materials production and processing in 2019.

Data according to above description	Non-Ferrous Metals Institute	Silesian University of Technology Organization and Management Faculty
1.1.	Yes	In partnership with other university entities
1.2.	Yes	Partially
1.3.	Yes	In partnership with other university entities
1.4.	No	No
1.5	No	In partnership
1.6	No	No
2.1.	Yes	No
2.2.	Yes	No
2.3.	No	Partially
2.4	No data	No data
2.5	No data	No
3.1.	Yes	Yes
3.2.	Yes	No

3.3.	No	Partially
3.4	No data	No data
3.5	Partially	Partially
4.1.	Partially	Partially
4.2.	Yes	No
4.3.	Yes	No
4.4.	No data	No
4.5.	Yes	Yes

Within 2017 - 2019, activities of the observatory were financed from public resources to high extent. In 2020, the project is continued however, the basis for the observatories network functioning is the already existing efficient cooperation of the key institutions and regional companies ready to engage their own resources for the purpose of transfer of regional information and knowledge between science, industry and self-government. The process continuously evolves and improves the technological observatory members offer. However, the analysis of current state has disclosed some gaps representing the space to overcome along the path to full development of a competence centre.

Summary

The performed analyses and studies were used to review the readiness for implementation of the innovation management model using the Competence Centre concept in the technological area of materials production and processing. It seems possible within the 2 - 3 year-long time perspective while standing up to the challenge of filling the competence gaps and assuming self-funding of own operations. The method this will be performed is the key. The fact that organizations build their advantage, including competitive edge, more often based on the created networks is a valuable inspiration. Cooperation competences are necessary in this case. Outlining the network approach assumption in the management sciences, presentation of traditional definitions and competences typology, defining cooperation competences: actual and network competences with consideration of their basic components provides the space for efficient operations.

The centre should be a valuable source of knowledge about cooperation options and potential partners that are to deliver new knowledge (Szmal A., 2016), support companies innovativeness through creating close relationship between research institutions and companies. The living labs plane is an important cooperation component, perceived as an experimental environment where the technology is created and tested under everyday life conditions, however the participants testing the new solutions are their co-creators. Living labs become an environment on the one hand and on the other a method for implementing and developing innovations. One of the milestones of the living labs development may be the accession to ENoLL - European Network of Living Labs (Open Living Labs). The network can be accessed by all organizations that use user-driven open innovations in their operations. Cooperation within Living Labs may be beneficial for a wide spectrum of innovative processes stakeholders in the region. Creating efficient living labs seems difficult, however in the Silesian Province there are many institutions that by engaging their own resources and capabilities or using the public support might organize effective living labs. Their creation is experimenting with the methods of using the infrastructure especially within the scope of principles of access to laboratories and determining the rates for using the infrastructure. Creating the living labs is therefore an evolving task wherein the optimum model of running operations and testing the solutions is achieved gradually.

Companies must look for innovations from different sources that would allow for developing their business model. When the absorption of ideas and new technologies is the integral element of a company business model, it creates an additional leverage for development of other business areas. When it is missing, other necessary elements allowing for converting the idea into a market value are missing too. Companies should be much more open to co-sharing the innovations or their licensing if they do not match their model. It is especially difficult to break the mental attitude barrier that consists in closing inside own structure. As proven by experience, attempts to cross this threshold is difficult but possible with participation of a professional intermediary. The intermediary can be innovation broker who is able to integrate the environments (triple helix) in the area of works related to innovation development, build a cooperation network, transfer technology, stimulate creativity and entrepreneurship. The main idea that should be used by the innovation brokers is the creation of innovation development on the supply and demand side. Exemplary tasks the knowledge brokers should implement within the scope of the basic objective:

1. Analysis of information needs within the scope of innovation development. (demand analysis: companies, business-related institutions)

2. Analysis of information within the scope of innovation development generated by universities, R&D entities, authorities (supply analysis);
3. Study of the development needs (creating new, improving the existing), competences related to creating, implementing and managing innovations. (supply and demand analysis);
4. Evaluation of system of information flow related to creating and implementing innovations; (demand, supply, institutional analysis).

These activities would correspond well with the increase of readiness for full-fledged application of the competence centre concept in the area of materials production and processing.

The innovation management model in the form of the networked Competence Centre would satisfy the basic task and would be able to utilize the resources of all its participants. However, this cannot be done without strengthening the mechanism of operations coordination by a competent leader. Openness to cooperation, innovations, openness to stakeholders interested in similar projects increases the chance for market success of commonly initiated, performed and implemented research and development projects.

Abstract

Dynamically changing environment influences the application of business models that use various types of innovations in the enterprises. They constitute one of the most important sources of creating the value, which is the condition for achieving competitive advantage and sustainable development of the organisation. Absorption and generation of various innovations often decide about the increase of the value for the client and stakeholders. The role of innovations in the increase of the value obtained by business models in chosen enterprises was studied in the paper. In particular the business models structure and their changes allowing for application of the product, process, marketing and organisational innovations were presented. The structural research on the marketing and organisational business models were conducted on the basis of the concept and rules of the so called New Era of Innovation. The ability of the enterprise implementing innovations for creating the increase and expansion of the value for the client in terms of using the right business model was evaluated. The objects of the case study were three enterprises, one of them being a service and trade company, the remaining ones the industrial companies. For the measurement of the value for the client and stakeholders obtained by studied organisations, the Balanced Scorecard standards were used.

Keywords: Business Model, Innovations, Value, Balanced Scorecard, Business Processes

Introduction

The basis of market success and development of the enterprise is its clearly defined business model. It constitutes a unique concept that defines the system of connections between the resources and the processes adequate for a given organisation, as well as its relationship with environment in creating the value. Design and application of new or modified business models, which component and attribute is the concept of generating the value, is more often based on innovations. It is innovation that is perceived as the source of various kinds of values important for the client. The strategy of sustainable development in three dimensions, that is economic, social and ecological, and the development of the Knowledge Economy (including Digital Economy) result in creating values strongly related and based on innovations.. Successfully applied, adequate innovation business models capable of absorption, creation and innovation diffusion are to make it possible. Obtained value decides to a large extent whether a given business model came out to be effective in implementation of the organisation's goals and achieving economic, market and social effects obtained by them. It also indicates its ability to implement various kinds of innovations that co-create both the value for the client and the increase of the economical value added (EVA, resources). The goal of this paper is to evaluate the dynamics of values obtained by business models, the sources of which are various kinds of innovations implemented by enterprises. Two research questions correspond with it. 1. What kind of changes in business models are caused by applied innovations? How does the value of a company applying innovations in its business models change? In the context of the set goal and research questions, for the assessment of the value generated by the business models, developed research methodology, which the most important elements were structural and comparative analysis of the business model conducted in the aspect of implemented innovation and the measurement method based on Strategic Scorecard, were used. In the paper, the research results were presented in the form of multiple case study. The first of the studied objects was a service and trade company, the second one was the producer of tie down straps and slings, the third one was the steel rolling mill.

Literature Review

The issues of business models bring a lot of attention of both theorists and practitioners of management. This interest is accompanied by various approaches and understanding of the business modelling (multitude of definitions

Cite this Article as: Jan BRZÓSKA and Arkadiusz SZMAL "Innovations as the Source of Creating the Value in Business Models" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

and concepts), hence the appearing postulates to create a common scientific platform for better and more effective research of the business models (Zott-et al.,2010).. Cognitive difficulties (definitions, structure) result from the fact of multi-dimensional and interdisciplinary nature of the business model. In relation to that, the research on it will be conducted from various perspectives, in different aspects, scope and depth of the research. Theoretical research on the business models (Kalinowski and Vives, 2013) is most often conducted in three perspectives: choices (strategic aspect), activity (organisation level), normative (operational level). Regardless of the approach to the conducted research, one of its elements is always the value category, its creation, transfer of ownership and recipients. Theoretical research on the business models should lead to its use in practice. Development of the research on business models has resulted in many of their definitions and concepts (Chesbrough, 2010, Dahan -et al., 2010, Teece, 2010, Zott-et al., 2010). In the context of presented research subject, the concepts related to the creation of the value and the meaning of innovation in business modelling are significant. Business model can be perceived as a system of configuration of the resources and mutually dependent actions concentrated on creating the value. The combination of such activities, resources, way of their organisation, and connections between the activities, resources , and the network of values, allowing for conducting these activities in cooperation with partners or clients, depends on the adopted business model. (Svejnova -et al., 2010, Zott- et al., 2010, Boulton- et al. 2000). Many considerations emphasise close relations between the business model and creation of the value for the clients and an enterprise, indicate the role of configuration of material and immaterial factors and the possibility to capture a portion of the income from the value delivered to the customers (Newth, 2012, Jabłoński, 2013, Boulton- et al. 2000). In the concepts of the business model, its two main dimensions are being exposed. The first one is the way of creating the value for the client, in particular which elements of the business model play the significant role and how this value will be implemented (Osterwalder and Pigneur, 2010, Gołębiowski-et.al. 2008, Chesbrough and; Rosenbloom, 2002). The second important business model is capturing the values for the enterprise that will give it an income (Afuah, 2004) . Its size depends to a large extent on the level of innovation, architecture, character and harmonisation of the resources and activities included in the business model (Zott and Amitt, 2010, Brzóska, 2014). A higher level of harmonisation between the elements of the system influences the increase of created value, and thus the possibility of its greater appropriation. Relationship between the value for the client and capturing the value is related to the networks of value and strategic choices being the components of the business model. Perceiving the business model as specific combination of resources makes it to generate the value through the transactions for both the clients and organisation (Chesbrough, and Rosenbloom 2002, Osterwalder and Pigneur, 2010). Stakeholders are being indicated as the recipients of the value, a term of creating and capturing the value in the network of values has also been introduced (Shafer – et al. Knop, 2015, Dahan -et al., 2010). Creating a unique value and competitive advantage is related to innovations carried by a business model (Hamel, 2002, Prahalad and Krishnan, 2008, Brzóska 2014). Innovations that are more often applied (Casadesus-Masanell and Ricard, 2011) allow to create the value for the clients (new products, new kinds of values, new methods of customer service) and the value for the stakeholders, e.g. environment protection, new technologies, new chains of values, or increase of the effectiveness (Dohn, 2014, Szmal and Jodkowski, 2015, Baran –et.al. 2015) Innovation, effectiveness, customer loyalty, complementarity (Zott and Amitt, 2010), as well as the processes and resources using innovations (Brzóska, Szmal 2015) can be perceived as the factors of creating the value in the business model. Implementing innovations is also supposed to prevent threats of imitation (Obłój 2002). The business models themselves may also constitute the organisational innovation important for the competitiveness (Hamel, 2002). Models of the Industry 4.0. can be the examples (Dobrowolska and Knop, 2020, Brzóska and Knop, 2020). In conclusion, the value based on innovation is a central dimension of the modern business model. The business model itself is a certain concept of logic of the company's functioning, capable of creating the value for the clients and the stakeholders, the sources of which are various innovations applied.

Methodology of the Study

For the assessment of the value created as a result of applied innovations and changes of the business models, the methodology of the study based on four basic components was used. It is presented in the Figure 1.

Fig.1. Research model

The analysis of the common environment and literature studies include: elements of modelling theory, innovation ecosystem, business environment, relations with partners, macroeconomic situation. The concept of the business model, the so called new era of innovation, was used in the structural and comparative analysis. (Prahalad and Krishnan, 2008)Apart from such elements of the model as: social architecture, technical architecture and business processes, creation of the value and type of the competitive advantage were included in the structural characteristics of the business model. The elements of the Balanced Scorecard were used for the quantitative measurement of the values obtained with the use of innovations (Kaplan, Norton, 1996, Blacha, Brzóska, 2016, Oslo Manual, 2005). The value created by innovations was represented by the results obtained in the following perspectives: financial, customer (market), business processes and development of human capital.

Analysis of Business Model Changes - Case Study

Company manufacturing belt slings (Company A)

The studied company (257 employees , sale amounts 10. 5million EURO) is a manufacturer of systems for securing and lifting loads. It operates in Poland since 1992. International company, operating in since 1935, is a shareholder. The production company manufactures belt slings, hose slings, single string rope slings, grippers, belts and chains fixing loads, provides advisory services within the scope of securing loads (over 23 thousand different product variants). Changes in the business model are presented in table 1.

Table 1: Characteristics of of the business model elements (Company A)

Social architecture		
	Period of the study: 2008-2012	Period of the study: **2013-2019**
Employment	Dynamic increase of employment to 216 (2012) employees Slow increase of engineering and economists share in the employment structure to 11%. Trainings within limited scope.	Systematic increase of employment to 257 (2019) employees Stable share of engineers and economists in the employment structure (ca. 16%). Wider scope and specialization of trainings comparing to previous period
Strategic competences	Trading competences: sale of fixing slings and belts, understanding of transport, construction and repair market, customer service.	Engineering and trading competences of production of slings , CRM, competences by design and advisory tasks, financial and risk management competences.

Knowledge resources	Limited scope of formal information and knowledge. Information and knowledge gained individually by employees (relatively narrow scope).	Information and knowledge gained individually by employees. Significantly increased range of formal information and knowledge (trainings, developed IT systems).
Technical architecture		
Material resources	Logistic and production infrastructure used to manufacture fixing slings and belts. Low level of equity. Good location of the company	Increase in equity. Purchase of modern equipment for belt slings production. Well organized procurement system.
ICT resources	Basic ICT. Information about clients and competition used in hidden knowledge	Controlling IT system, CRM system, ERP system production, digitization of business processes (industrial scanners),
Processes and creating the value		
Business processes	Purchase, production, sales , marketing, HR (basic). Outsourcing of transportation services.	Service, trainings for clients, purchase, production, lean manufacturing. Sales and CRM. Designing and advisory, HR, risk management.
Attained competitive advantage and its sources.	1. Competitive advantage in the quality of offered products attained by means of the implemented quality standards. 2. Competitive advantage resulting from location.	1. Competitive advantage resulting from professional service and design 2. Competitive advantage resulting from availability. 3. Competitive advantage resulting from innovations.
Creating and features of the value	High quality products securing the loads. Competitive prices. Well-known brand, a simple value chain - based on effective production and wholesale trade	Developed value chain. High quality and safety, flexible forms of purchase. Short lead times, professional advice. Competitive prices of a wide range of products.

The studies show that different types of innovations (process, product, organizational, marketing) are used in the change of business processes. Innovations improve business processes, which use and develop many elements of social and technical architecture In the investigated company, development of human resources is noticeable. Employment dynamics is accompanied by beneficial changes of its structure and growth of competences, especially marketing and engineering. The number of business processes increased, because of the EU funding, new technology and production devices were implemented. Table 2 shows the results obtained from the BSC perspectives.

Table 2: Results attained in the BSC - companies: A.

Financial perspective					
Result	**Measure**	**2008**	**2012**	**2015**	2019
Economic value added (EVA)	Million EURO	0.58	0.39	1.12	1.32
Return on sales	Net profit /sales (%)	12.1	17.4	22.1	20.7)
Return on assets	Net profit /asets (%)	22.4	14.2	23.2	21.2
Net income dynamics	Previous period = 100	100	112	162	128
Client's perspective					
Level of customer satisfaction	Percentage of satisfied customers	no data	86.5	93.2	94.5
Level of customer loyalty	Number of regular customers	19	18	54	68
Strategic customer value	Average sales/ Number of	6.1	8.1	15.2	19.3

	strategic customers (thousand EURO				
Sales dynamics	Previous period = 100	100	112	134	128
Processes and technical resources perspective					
New product offers	quantity	no data	10	35	44
Services quality increase	Decreased number of complaints (%)	0.8	0.6	0.6	0.2
Increase in the number of new processes	quantity	0	1	4	3
Increase of the value of machines and equipment	Increase (%)	2.4	3.2	189.3	72.2
Human capital development perspective					
Innovativeness of employees	Number of registered innovative solutions	0	2	5	4
Increase in employees productivity	Value of sales per 1 employee (thousand EURO)	20.3	22.4	36.6	40.8
Personnel qualifications	Number of engineers and economists	17	23	32	40
Employees satisfaction	Percentage of satisfied employees	no data	72	72	74

Growth of effectiveness is noticed and confirmed by EVA, dynamics of growth and sales profitability. Very good results obtained in 2015 must be noticed, which is a result of full implementation of product, marketing, process and organizational innovations. In this case, one can say about achieving synergy effect of the applied innovations. One must notice high dynamics of sales attained within the last years. The company maintains high level of clients satisfaction, number of regular clients increased together with the value of sale per 1 strategic client. . Implementation of innovations caused rapid increase of product offer. Quality improved slightly, number of new processes and value of technical equipment increased, which fact is related to product and process innovations. In this case, one can say about achieving synergy effect of the applied innovations.. Significant increase of productivity is a major achievement for the company..Despite the progress of innovativeness, it is difficult to consider the number of innovations reported by employees as achievement. The level of employees satisfaction is stable and can be considered as satisfactory.

Trading and service company of metallurgical products (Company B)

The company has been operating for 15 years and employs 118 people. In 2019, it achieved the level of sales around 7.8 million EUR. Since 2012, innovations have been implemented, the company changed its business model, and in addition to trading, it opened service centres. Implementation of innovative processes allowed for introducing new products on the market and changing the relations with clients. Elements of business model given in the Table 3 allow for comparing and assessing changes made as a result of innovations.

Table 3: Characteristics of the business model elements - Company B

Social architecture		
	Period of the study: 2008-2012	Period of the study: **2013-2019**
Employment	Reduction of employment to 75 employees. Trainings within limited scope.	Stable employment at the level ca. 120 employees. More employees with university education, both economic and technical.
Strategic competences	Sales of metallurgical products and construction materials, customer service: Competences of cooperation with metallurgical products manufacturers.	Engineering and trading competences: service of metallurgical products. CRM, designing and advisory competences, financial and risk management competences. Construction of prosumer contacts.
Knowledge resources	Limited scope of formal information and knowledge. Significant meaning of hidden knowledge application.	Significantly increased range of formal information and knowledge (trainings, developed IT systems and CRM).
Technical architecture		
Material resources	Logistics and property resources used during retail and wholesale sale. Relatively low level of equity. Well organized supplies system. Good location of trading warehouses.	Increase in equity. Modern devices for plastic working, metal working and production of steel structures.
ICT resources	Basic IT solutions within the scope of accountancy and sales. Information about customers and competition used in hidden knowledge (narrow scope)	IT systems (industrial scanners, cloud computing), controlling, CRM, engineering designing and modelling systems, metal working control systems, service platform
Processes and creating the value		
Business processes	Sales of metallurgical products, marketing on the metallurgical products. HR (basic). Outsourcing of transport services.	Metallurgical products service, procurement, production of metallurgical products, designing and advisory. Insourcing of transportation services. HR (professional). Controlling, risk management process
Attained competitive advantage and its sources	1. Cost competitive advantage in obtained because of relatively low fixed costs and competences while purchasing metallurgical products. 2. Competitive advantage resulting from location.	1. Competitive advantage resulting from a wide range of services and competences. 2. Quality advantage
Creating and features of the value	Standard quality and competitive prices for metal and construction products	High quality and wide range of services. Professional advisory and design. Fast order processing and delivery to the customer.

Observed dynamics of the business model shows significant changes in its structure. The structure and competences of employees changed, new processes, resources and products were introduced. This was related to application of many innovation types. They allowed for creating new values for the client and competitive advantage.

The results presented in BSC (table 4) show that the implemented innovations improved profitability, a growth in net profit was noticed, the company achieves satisfactory economic value added (EVA), meaning that

Table 4: Results attained in the BSC – Company B.

Financial perspective					
Result	**Measure**	**2008**	**2012**	**2015**	2019
Economic value added (EVA)	Million EURO	*-0.19*	*0.11*	*0.35*	0.41
Return on sales	Net profit /sales (%)	*3.3*	8.4	18.2	14.2

Return on assets	Net profit /asets (%)	*2.4*	7.2	13.1	10.2
Net income dynamics	Previous period = 100	*100*	112	172	146
Client's perspective					
Level of customer satisfaction	Percentage of satisfied customers	75.5	*80.0*	*86.2*	92.2
Level of customer loyalty	Number of regular customers	*98*	*92*	*142*	168
Strategic customer value	Average sales/ Number of strategic customers (thousand EURO)	*7.2*	*8.2*	*14.6*	13.8
Sales dynamics	Previous period = 100	*100*	118	*194*	176
Processes and technical resources perspective					
New product offers	quantity	*18*	*24*	*66*	54
Services quality increase	Decreased number of complaints (%)	*1.4*	0.8	*1.0*	0.7
Increase in the number of new processes	quantity	2	2	7	5
Increase of the value of machines and equipment	Increase (%)	*11.2*	21.3	272.2	76.4
Human capital development perspective					
Innovativeness of employees	Number of registered innovative solutions	*0*	*3*	4	3
Increase in employees productivity	Value of sales per 1 employee (thousand EURO)	*31.1*	*38.4*	50.2	66.1
Personnel qualifications	Number of engineers and economists	*34*	*36*	65	67
Employees satisfaction	Percentage of satisfied employees	no data	78	*79*	84

its value increases. The profitability of the assets slightly reduced due to investments (supported mostly with EU funds) in to new innovative processes. They allowed for introducing new products leading to significant growth of sales and twice increase in productivity. Marketing and organization innovations and the created value contributed to maintaining clients and considerable increase of their satisfaction. The number of educated employees increased, however their innovativeness is still low meaning that the company uses open innovations.

Hot rolled steel products rolling mill - Company C

The metallurgical company is a manufacturer of long steel products and employs ca. 200 employees with the level of income about 48 million EUR. For many years the business model was based on production of a narrow spectrum of long steel hot rolled products. The business model changed in 2014 after introduction of new technologies (process innovations) allowing for production of new products (product innovations). Table 5 presents characteristics of the business model elements.

Table 5: Characteristics of the business model elements (Company C)

Social architecture		
	Period of the study: 2008-2013	Period of the study: **2014-2019**
Employment	Stable employment (approximately 250) and its structure. Low share of university education employees.	Stable employment (230-240). Increase of engineers and economists number.
Strategic competences	Production of metallurgical long rolled products. Cooperation with domestic suppliers and wholesalers	Purchase of the charge on global markets Marketing, CRM, designing and producing steel structures, controlling (including BSC)
Knowledge resources	Limited scope of formal knowledge and information. Narrow range of technical and commercial knowledge.	Increased scope of formal information and knowledge (training). Increase of technical and managerial knowledge resource
Technical architecture		
Material resources	Property resources at average technical level used for production of typical long products. External logistics of purchase and sales. Good location.	Utilization of the capital mix to purchase modern technologies and production of perforated sections and service of metallurgical products.
ICT resources	Basic IT solutions within the scope of production control, accountancy and sales.	Using cloud computing. Using digital platform for trading and service
Processes and creating the value		
Business processes	Production and wholesale of metallurgical products, purchase of the charge. HR - limited trainings.	Production of innovative long products, service of metallurgical product, HR-motivation system related to effects, more trainings, CRM, ISO, controlling, risk management.
Attained competitive advantage and its sources.	The competitive advantage is based on price / standard quality ratio concerning manufactured steel products .	The competitive advantage is based on differentiation (new products) and flexibility of services.
Creating and features of the value	Value resulting from the quality standard / price ratio. Fast completion of orders and good location.	Creating the value based on effective production of wide assortment of long steel products Competitive prices of steel products assortment.

Using equity, credit and EU funds to invest in new technologies and products (perforated sections). Modern technical devices for servicing metallurgical products (cutting, machining, bending). Introduction of ISO, CRM and BSC, developing of HR..

The results presented in table 6 in the form of BSC show that the company shows financial stability. Implementation of innovations did not significantly improve the financial results, but controbuted to their maintenance. The number of regular clients slightly changed and the level of client satisfaction improved. Sales and productivity grows systematically, the number of new processes and products grows since 2015. The company corrects the employment structure, there is a growth in satisfaction from work, however alike in company A and company B, the level of employees innovativeness is low.

Table 6: Results attained in the BSC – Company C

Financial perspective					
Result	**Measure**	**2008**	**2012**	**2015**	2019
Economic value added (EVA)	Million EURO	2.2	1.7	1.02	2.6

Personnel qualifications	Number of engineers and economists	7	11	16	21
Employees satisfaction	Percentage of satisfied employees	no data	83	86	89

Conclusions

In the context of the first research question, it is clear that the innovations applied by the studied companies have changed the resources (mostly material) and processes within the business models which fact allowed for creating new value for clients expressed in the sales of new products. Management changes focused on improvement of clients service (CRM) and development of knowledge management (HR and ICT). Based on innovations, the companies augmented the value chain by better adapting it to clients' needs. Quantitative measurement of value show multidirectional impact of innovations on the results within all perspectives. The financial and client perspectives were mostly affected by marketing and product innovations and the business processes and technical resources - by the process innovations In turn, the organization and process innovations had the strongest impact on the results obtained in the human capital development perspective. Comparative analysis of the obtained results representing the created value in the business models shows similarities of the innovation impact on the improvement of economic and market situation. The innovations contributed both to the increase in sales and profitability. To answer the second research question, based on the obtained results, the innovations led to an increase (or stabilization in worse case) in EVA and assets (mostly equipment) that represent value of the company. The result of the business

model application is the creation of multidimensional value that translates to the achieved company's results. Their measurement represents an important instrument that allows for evaluating effectiveness, competitiveness and efficiency of the implemented new business models or changes in the functioning models. According to the paper objective, the performed studies showed that application of the method that uses the structural analysis and BSC to evaluate dynamics of the value achieved by the business models based on various innovations is justified. The presented methodology can be used to wider extent to study the relationships between implementation of innovations and creating value by the changing business models. Such a research approach provides multi-aspect evaluation of the innovation role in creating the value by business models of companies, which might play a significant role, especially in modern business models, e.g. Economy 4.0.

User Analytics as The Novel Approach Towards Personalization and Adaptation: Rudiments for User-Tailored Design

Gracja NIESLER [0000-0003-3309-7219]

Wroclaw University of Economics and Business, Wroclaw, Poland
gracja.niesler@ue.wroc.pl

Abstract

Dictum "*Scientia potentia est*", credited commonly with the sixteenth century philosopher Francis Bacon, in the modern world of information seems to be even more true than ever. Humans as the information consumers and producers have created the market, where even sensitive, personal data can be trade objects. Every web application keeps track of our activities, every browser saves searching history and every social platform collects information about our relations and interests. That kind of knowledge can serve many purposes. The least of the users per se. The main beneficiaries are marketing and sales activities targeting potential customers. Nevertheless, if we look into health informatics or e-learning, a new potential of data usage emerges. The great amount of information can give more comprehensive scope on patient condition in order to recommend more adequate treatment. As in the learner's case the innate predispositions and learning curve indicate suitable teaching methods. Although intelligent solutions are applicable practically in every aspect of life, for many systems, still the benefits are not tangible, therefore developers and business owners do not find them profitable enough. It requires consecutive change in the way of thinking in terms of designing information systems in the user-centred paradigm. While we experience dynamic growth with ubiquitous expansion of the intelligent solutions and technologies, the new paradigm of user analytics for user-tailored design, and the areas that it can contribute to, is still yet to come.

Keywords: User Analytics, HCI, UX, personalization, adaptation, adaptive systems, intelligent systems, user-centred design, user-tailored design, Kansei, inclusive design, big data, psychometrics

Introduction

The advances in Human-Computer Interaction deliver many means targeted into facilitating user's functioning both in virtual reality and in the outside world. The issue of interaction includes activities related to a constant improvement of the dialogue between human and a machine. It has been striving to ensure that both software features and hardware devices be receptively directed to satisfying the needs of the user, and the computer be a legitimate partner in the joint effective acting. In a far-term perspective, the machine is supposed to be functioning like a human, and interaction should take on the features of natural communication. In recent decades we have stepped into the era when emotions crucially matter. The expansion of social media allows introducing the affective human factor into interactions between users and systems. Hence the users differ on psychological and cognitive level it is crucial to provide adaptability that particularly answers to users' individual, personal needs.

The aim of this paper is to introduce the scaffold of **User Analytics** (**UA**) concept as the approach to more flexible adjustment to user's needs in user-tailored systems. The paper consists of following sections: introduction, background and interpretation, user nature and levels of analytics, personalization and adaptation for interaction design, user-tailored design, discussion and further research, and conclusion. The background section presents the definition of User Analytics and related work context, on the basis of interdisciplinary approach in the domain of Human-Computer Interaction.

The next section presents human nature elements used for the analytical process, especially mental model building and analysing personality as the attitude towards outer world, information processing, learning, problem solving, decision making and organizing the environment. The analytics as the process of gathering, clustering, transforming and presenting data, discovering models and patterns, predicting behaviours can be conducted on the level of simple interactions, complex action sequences, preferences discovery and organization, psychometrics and social context. The results of comprehensive analytics of user data delivers the basis for personalization and adaptation, which is presented in the next section of the paper.

Cite this Article as: Gracja NIESLER "User Analytics as the novel approach towards personalization and adaptation: Rudiments for user-tailored design" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

User nature should be the main field of study for designing systems in the user-centred paradigm. Whereas the user-tailored design provides "perfect-fit" for the individual user, according to a wider range of needs than just functional and visual preferences. That indicates the necessity of the aspects of user experience design to be transposed into the act of quantifying the user for interaction adaptability purposes. The adaptation in user-tailored systems can be active or passive. Both require defining user archetype, model and profile to predict the behaviours and expectations in order to provide optimal flexibility. The system should stay alert and the analysis results should be under constant process of fidelity verification.

In the user-tailored design section the rudiments and requirements are to be presented. The user should be able to use any information processed by the system and its presentation in a way that supports perception, awareness and perception of the situation as well as understanding. The basis for user-tailored systems is highly advanced adaptation of its interactions to not only explicit but also to the tacit needs. In that case the persona design in user modelling seems to be insufficient, therefore further research towards user analytics is required. It is connected with practical and ethical issues being discussed in the final sections of the paper. The most important message is not to harvest users but serve them.

Background and interpretation

Recently, along with the massive flow of information and its accessibility, the new paradigms and techniques of processing have emerged. The term big data does not simply refer to large amounts of information, but the usage of technology of processing and delivering to the users in exact form in order to help them solve real life problems. The significant issue with the big data concept is the analytics. There can be different kinds of analytics: descriptive, diagnostic, predictive and prescriptive, according to its purpose. Descriptive analytics provides probabilities and trends based on existing patterns; diagnostic is used for searching the root cause of a problem; predictive uses artificial intelligence to forecast scenarios about possible outcomes and prescriptive analytics uses the retrieved parameters to propose best solutions (Riahi i Riahi, 2018).

The data about humans using information systems are substantially heterogeneous, due to the complex and fuzzy nature. Therefore, the big data concept is the most relevant. In that context we can say that User Analytics refers to gathering, organizing, processing, visualizing and using data about the user, as in any analytical approach. Nevertheless, the data and its relationships do not represent the true reality, lacking very often the aspect of causation and "nuanced human narrative that underlies a dataset" (Applen i Stephens, 2018). The focus is being put, withal, on particular purpose and data category, which is all about user quantifying and user data mining.UA thus provides the human-side aspect and can be used for detecting patterns, predicting actions, making decisions (by the system) about interactions and personalization and adaptation. However, it highly requires the artificial intelligence solutions application.

The User Analytics domain is set within an interdisciplinary area (see Fig.1) and benefits from the achievements of the following research fields: human-computer interaction, user-centred design and user experience, artificial intelligence, psychology (including sociology) and psychometrics, big data and predictive analytics.

Fig.1. User Analytics domain as an interdisciplinary research area

Human-computer interaction (HCI) is the base area, because it includes concepts, methodology, techniques and tools providing the communication between user and the machine. For the UA perspective it includes both analysing the user interactions and providing the adjusted responses from the system. From the software engineering point of view, the user-centred design (UCD) provides the human-oriented perspective, especially including the aspects of User Experience, which supplements the design process with the awareness of subjective, complex and dynamic issues of usage of technology (Harutyunyan i Riehle, 2019). In terms of User Analytics user experience design (UXD) should be focused not only on delivering a positive experience to the users, but also retrieving crucial information about the user's reactions for analysis purposes, in order to improve interaction.

The potential of analysing the users' behaviour has increased in the recent years. For example, in marketing and advertising in the last decade the click-through rates (CTRs) as an information from potential customers have appeared to be not sufficient, and the data from social platforms such as reviews, tweets, followers, clicks and likes became an abundant territory to (Prabhu, Chivukula, Mogadala, Ghosh, & Livingston, 2019). In the nearest future probably other application areas will benefit willingly from the extended analytics. Therefore, a human being as the main field of study requires a psychological approach, and transposing the profile into the psychometric characteristics.

User nature and levels of analytics

Despite many business companies or developers are not much interested in deep user analytics, apart from the information for sales and marketing purposes, now there is a time of very competitive market, especially of mobile applications, and therefore that is the user engagement, which determines the application's success. The fundamental aspect of analytics is its causality, and thus the answer to the question: why and for what purpose people use the applications? Technology provides support and facilitation of human's functioning in the real world. That means that computers need to adapt the functionality to the user's natural environment. Therefore, the primary research area in user-centred design is the user nature, especially connected with reality experience and coping with the real-life problems.

Applications became very personal due to ubiquitous computing and its support in everyday life. Therefore, we focus especially on UX design, according to fulfilling the goals of usability. Analytics can retrieve information from both aspects – if it is usable for particular user and what kind of experience they are having.

The usability and UX present different aspects of use-centred design. Usability is part of objective quality in design, and UX is related to the objective and subjective quality in use. It is crucial then to understand the factors influencing the degree of satisfaction in the real context of the product usage. Therefore, the evaluation methods for usability should be used during the design, and for the UX – during usage (Kurosu, 2017). The proposed concept of analytics can help with the UX evaluation.

We ought to have in mind that users crucially differ, according to plethora of characteristics located in abilities, preferences, predispositions, difficulties, impairments, personality, affections and emotions. Mainly, the user's goals are: learning, problem solving and decision making, as the elements of cognitive reality experiencing, and they determine the objective quality in design for usability (Fig.2). The personality is described as the composition of the three factors: thoughts, feelings and behaviour, which affect the User Experience. Thoughts are responsible for the attention and engagement, and behaviour influences the way of organizing life and tasks. It all represent the objective quality in use. The subjective value in user is represented by impressions, judgement and affective response, derived from feelings and related behaviour.

Fig. 2. Application of user nature elements in design and in use

For defining predispositions, which determine the cognitive process, as innate ability to percept and process the information, we can use the combination of learning determinants (memorizing, understanding and content association) and types of intelligence (which represent brain's tendency to particular patterns of problems) (Niesler & Wydmuch, 2008).

The personality identification is not easy, and many wrong diagnosing results may occur while conducting analytical process. Therefore, it has to be interpreted very carefully. Moreover, there are more than one theoretical background for identifying personality. For our previous studies we have used Myers-Briggs Type Indicator, based on Jung's type, which helps describing preferences as mental functions connected with attitude toward outer world, perceiving and processing information and organizing life (Niesler i Wydmuch, 2009).

For affective aspects the deeper analysis is required. Using, for example, the Big Five traits (such as extraversion, neuroticism, openness, conscientiousness, and agreeableness) it is easier to predict the user's reaction and behaviour, even the negative one, like in case of the neuroticism. Nevertheless, there are some exceptions linked to personality disorders, for example according to the Dark Triad traits (narcissism, psychopathy, and Machiavellianism), which can impede and falsify the results by the deceptive behaviour (Furnham, Richards i Paulhu, 2013).

For gaining relevant data the analytics should be conducted on different levels, according to the purpose. For the system adaptability we use different kind of data. According to the typical user characteristics (age, sex, location/ethnicity, disability, culture, etc.) we can use simple predictions of requirements and needs. In the cognitive aspect the basis is the learning curve analytics, especially analysing the results and choices. The personality aspect is more complex, because we need to perform the data extraction from the interaction analysis. It can be conducted on the following levels:

- simple interactions,
- complex action sequences,
- preferences discovery,
- psychometrics,
- social context.

In the health industry we have problem with the indirect user (e.g., a doctor), who is the receiver of the information, but the data, which are being processed, concern a patient. In that case the adaptation is not based on indirect user's preferences, because the health monitoring feedback is general. In case of *mHealth* the possibility of personalization is more open, because "the individuality is not limited to the sensor data, but also to the user who is using it" (Siddiqui, Koch, Rabie i Handmann, 2014).

In every aspect of user data analytics, the privacy and sensitive data protection is crucial. We have to remember that data misuse can bring serious harm, especially while "the UX industry lacks ethical guidelines and standards or even a governing body that enforces any kind of universal framework of ethics" (Fong, Waycott, Kadir, Gispen i Nacke,

2020). Therefore, the User Analytics should, in particular, include principles, standards and guidelines for the use of personal data.

Personalization and adaptation for interaction design

The way system acts and responds to user behaviour lays in the interaction design. The personalized and adaptive interaction design requires complex user data analytics. The analytics is a cycle process, including following steps: capturing, reporting, model prediction, acting and model refining. The result of comprehensive user data analytics delivers the basis for personalization and adaptation. We define adaptability as the application's ability to react to user's behaviour and to adjust the actions accordingly to the user's expectations and individual needs. The system can adapt the functionality, presentation of information or behaviour.

The way of executing adaptation process inclines different modes: passive and active. The active adaptation is based on constant monitoring the user's interactions, and redefining patterns and predicting user's further behaviour. The passive adaptation is being executed mainly on demand of a user or prerequisites and pre-set conditions (Niesler & Niesler, 2020). The patterns depend on the analysed characteristics (for cognitive or psychological aspects). The objective and subjective values determine the assessment in design or in use. It is connected with the process of adaptation, which exhibits behaviour when is in use (run-time), which is a result of the decision made in design-time (Niesler A. , 2020). The personalization provides the models that are analysed.

User Analytics process plays crucial role for interaction design based on personalization and adaptation (see Fig. 3). The personalization part is responsible for defining the domain of a user for analytics, and the adaptation is the system's response for the results of the analysis. The capturing stage selects and organize data into models and patterns. The most basic is the user archetype, which represents elemental characteristics and innate predispositions. The archetype is a model which is rather static and does not change for a long time. Nevertheless, it should also be a subject of periodic verification. It is related to the objective value in design, and the adaptation is usually passive, on the functionality level defined in the design-time.

Fig.3. The model of UA process for interaction personalization and adaptation

The user profiling refers to the objective characteristics in use. The analytics should be conducted in the real-time and the patterns need to be constantly verified. The application analytics uses historical or real-time data to adjust its behaviour in order to offer the best-known recommendations, tailored to the current situation of a particular user (Niesler i Niesler, 2019). The next stage of analytics is reporting on extracted and verified patterns, trends, and especially exceptions. The user can follow or reject recommendation. It requires the ability for a user to explicitly influence the system's adaptive behaviour, which can be done by observing common interface elements like undo button or hotkey (Schmidmaier, Han, Weber, Liu, & Hußmann, 2019).

For the presentation and behaviour adaptation, based on the results of statistical regression data for trends and machine learning, the UA provides models and patterns prediction. Especially for the interaction profiling, which determines subjective characteristics in use. The adaptive system behaviour can be a recommendation to a user or the automated changes in the interaction (the acting stage of UA), then the user's reaction is being analysed, and further actions can be predicted. The analysis is the most dynamic at this stage, because many errors and miscalculations may occur and frequent models and patterns assessment is required. Moreover, the subjective parameters are difficult to identify, because of the external interferences, which may disrupt the true value. The area of the interaction patterns mostly depends on the affective factors and it's hard to predict. There is a necessity of collecting a large amount of data for proper patterns creating and further predictions of possible behaviour. It leads to the models and patterns refining for the next round of analysis.

The crucial element of the analytical process, which is different from the traditional data analytics cycle, is the module for fidelity level monitoring and verification. It is being conducted on every step in the analytical process. It checks the probability of natural pattern change, as a part of evolution, based on similarity to previous instances and the deviation from the potential growth curve. In case of intelligent tutoring systems, it would be a learning curve for the particular learner in the specific area in the learning course or program. It means that a system has to be alert to any changes in the model variables, and user's behaviour. Each model needs to be validated for credibility, before moving to the next stage of analytics.

The main problem is satisfying and fulfilling user's emotional needs (according to *Kansei* design), and especially translating it into the product design variables, for the neural network algorithmic (Guo, Qing-Xing Qu, Chen, Ding i Liu, 2015). Apart from many issues on the cognitive and technological level to solve, there are still the organizational and conceptual problems in the approach to the adaptive design. Therefore, we need to take a closer look to the user-centred design paradigm.

User-tailored design

User-centred design has given plethora of guidelines and techniques to focus on user's needs in creating usable products. The appearance of User Experience concept has extended usability to satisfaction and positive reception. Nevertheless, the advancement in technology and its coexistence with humans in everyday life induced the necessity of the products to be more personalized and adaptive. Hence the design paradigm needs revaluation and extension both in the approach and methodology into user-tailored design (UTD).

The most common technique for representing user's preferences in UX design is creating personas. "Persona" derived from Latin, and also from the Greek word "prosopon", meaning theatrical mask, understood as an object not 'necessarily modelled on truth, but being a form of presentation and performance for certain effect' (Marshall i Barbour, 2015). Following that lead, personas represent the vision of the developer or designer, but not the actual, individual preferences and characteristics of particular user. By using User Analytics, we should provide the user-tailored interaction, which operates on a living organism of the user, in the real-time analysis and adaptation.

The basis for user-tailored systems is highly advanced adaptation. In contrast to UCD, user-tailored approach is rather a design on meta-level, not for a particular customer, but rather focused on problem domain and purpose of an application. It is more suitable for wider range of recipients, just like mobile applications. So the design process should be conducted that way. However it does not exclude the UCD agile techniques, but needs focusing on pre-design research, and then on the creating patterns, by analysing data just as they occur. Nevertheless, the foundation of UCD is crucial and sets the direction for further research. The user-centred design is set by the following general principles (Case, 2013) (Gulliksen, et al., 2010):

- Focus on a user and their goals of the activity should guide the early development;
- The involvement of representative users throughout the product lifecycle;
- Evolutionary systems development – iterative and incremental product development;

- Simple design representations dedicated to users and stakeholders;
- Prototyping – early and continuous prototyping in cooperation with end users;
- Usability goals and design criteria to control development;
- Explicit and conscious design activities – design directly related to user interface;
- Multidisciplinary design teams;
- Usability experts should be involved throughout the design process;
- Holistic, inclusive design – all future use aspects to be developed in parallel;
- Processes customization – adaptation UCD to local conditions;
- Establishing a user-centred attitude throughout the project team and client.

The main elements of the user-centred design include observation, including creating personas and scenarios, prototyping and testing. Fig. 4 presents comparison for the UCD and user-tailored design approach.

Standard elements of user-centred design	USER-CENTRED DESIGN (UCD)	USER-TAILORED DESIGN (UTD)
FOCUS	impact put on the interface (interaction) design	impact put on analytics and adaptation
OBSERVATION	analysing user's task as a part of design process	pre-design research (interdisciplinary approach)
PERSONAS	examples of potential users; applied objective characteristics in design and in use	mental models and patterns of personality types; applied subjective characteristics in use
SCENARIOS	scenarios related to personas	scenarios related to analytical adaptation process
PROTOTYPING	usually low fidelity prototyping for receiving the feedback from potential or dedicated end-user (cheaper, agile approach); dedicated to the users and takeholders	required high fidelity prototyping in order to to validate and verify the analytical process (expensive, rewearch approach) dedicated to designers and researchers
TESTING	iterative, engaging end-users in the design process	requirement of big data analytics to verify the patterns learning and prediction

Fig. 4: The comparison of UCD and UTD approach

There are some approaches that go beyond the standard UCD guidelines, especially since practicing UX design. Enriching the personas modelling with refining and validating persona and scenario assumptions, based on quantitative and qualitative user data (Coorevits, Shuurman, Oelbrandt, & Logghe, 2016), digital human modelling, manikin characters, inclusive design and human behaviour modelling (Case, 2013), is a significant support on different level of interaction design.

The user-tailored design requires advanced analytics, because it is mainly focused on identifying user's tacit needs. It means that the user themselves does not have sufficient knowledge about the human nature to propose the solutions by themselves. We can formulate main guidelines for the scope of user-tailored design for adaptive systems:

1. The foundation for design is human nature – trying not to guess who the user might be, but using experiential approach;
2. Being opened for every possibility in design, even the least probable, to design exceptions for machine learning;
3. Impact not put in the interface design, but on data processing design;

4. The interaction is a result of personalization and adaptation
5. The prototyping should rather be of high fidelity – not focused on display but correctness of predictions; checking the user's reactions to the aesthetics and layout is a secondary issue, and rather should be available for the passive adaptation – users can adjust the display freely, as they incline;
6. Testing, especially in the early stage of design process – for possible behaviours, on a very large group of users (to learn the system the probable patterns), and verifying accuracy of adaptation process – focused especially on the objective and subjective characteristics in use;
7. Mainly focus on active adaptation – probable situations not from scenarios and personas, but from the activity of a user (on research stage);
8. The designer cannot predict all the situations – the intelligent system adaptation should 'learn the user nature';
9. Necessity of AI application;
10. Providing the automated fidelity level verification.

There is a necessity of combining tools and methods for more comprehensive outcome. The level and complexity of applying analytics depends on the purpose of the application.

Discussion and further research

Applying User Analytics requires comprehensive approach and inclusive design in the user-tailored paradigm. The concept of inclusive design is based on the convincement that humans are naturally very diverse. That wide scope brings some restrictions to the UCD products, such as the lack of awareness of universal design and especially the lack of knowledge about user needs among the designers. (Abascal & Azevedo, 2007). Nevertheless, providing universal, comprehensive analysis for the inclusive design may bring ethical and social risks issue.

The subject of User Analytics, and the concept of UTD require solving many problems connected with ethical and practical issues, adaptation to direct and indirect users, and especially the problems concerning data acquiring, which correspond with tacit needs and subjective characteristics in use.

Many of the technological advancement may work to the advantage of solving some problems in the UA area. For example the eye tracking technology can be used to collect objective data for user experience on smartphone application, which should reduce the bias in subjective questionnaire-based measure of user experience and could be used to detect weights for design variables for user interface design (Qu QX, Zhang, Chao WY i Duffy, 2019).

Conclusion

In the presented paper the theoretical concept of a practical problem has been proposed. In current times of technology development we can see the necessity of more adaptable products. It cannot be done without advanced analytics and the paradigm change to the user-tailored design. The comprehensive approach requires wider, interdisciplinary research for inclusive design.

There are still some barriers on business and technological level. For now the application of UA for application adaptability is possible in health and education. *MHealth* may apply advanced analytics for adapting the monitoring and treatment for special user's needs, and even a consideration of empathy throughout the re-design process, enabled through a contextual understanding of users, their needs, and their environment (Farao, et al., 2020).The application of UA in intelligent predisposition-based tutoring systems derives from the differences in human nature, character and individual predisposition for learning, which imply what sort of teaching method should be applied towards a particular human being. Leveraging the adaptation to user's needs, the meta-learning analytics with predisposition-oriented approach, can be more effective than the traditional tutoring (Niesler & Wydmuch, 2008) (Niesler & Niesler, 2020).

Abstract

The total amount of data produced in the world is growing at a very fast rate, however, the increase in data storage capacity and the revolution in storage support is much slower than that of data generation. How to store, archive and process such a large amount of data becomes a critical and difficult challenge. Researchers believe that they have found a solution to this problem by analyzing the chemical processes that occur in the body of animals and also in plants. Among these processes, animal and plant cells can store or exchange data from one cell to another systematically, and the storage process happens in each cell using a molecule called deoxyribonucleic acid (DNA). The storage capacity of synthetic deoxyribonucleic acid (DNA) make it one of the promising candidates for archival storage systems. In addition, the high density, large capacity and long-term stability of DNA molecules make them an emerging storage medium particularly suitable for long-term storage of large data sets. In this paper we present the technology of DNA storage which aims to optimize the storage of masses of data or what we call Big data. We study its storage capacity when it comes to a huge amount of data as well as its operating principle and its added values compared to available technologies.

Keywords: Storage, Big Data, Chemical processes, DNA

Introduction

The World Wide Web presented by (Berners-Lee, et al., 1994) has transformed the way of creating and sharing information between human beings and breaking down all cultural barriers. Several emerging communication technologies (e.g. 5G and Internet of Things) have enabled seamless connectivity and new applications. As a result, the increase and explosion in the amount of data generated and stored has led to new challenges in data storage technologies. Currently, all of this generated data is stored in large data centers, which has resulted in significant investments in cloud services and infrastructure (Miller, 2013). In addition, traditional storage methods face major challenges in storing and processing massive amounts of data. In order to solve these problems and satisfy the demand for storing massive amounts of data, a promising approach has emerged which consists of storing the data in deoxyribonucleic acid (DNA). DNA as a storage medium has become an attractive choice due to its high spatial density and long durability.

(Davis, 1996) mentioned that the idea of storing data in synthetic DNA strands (sequences) has been around since 1988 and research into DNA-based data storage has grown rapidly in recent years with the development of technology. of DNA synthesis and sequencing. DNA storage has some competing advantages such as long durability, extremely high density and low power consumption.

Deoxyribonucleic acid (DNA) naturally contains the genetic program for the biological development of life. Fundamentally, DNA can also be used as a compact storage medium for petabytes of encoded information. The potential benefits of DNA storage include: stability at moderate temperatures, biological replication, research and biological indexing, and extremely high density beyond the order of terabytes in 1 gram of DNA.

The article is organized as follows; we first briefly present DNA storage technology as a future solution to Big Data storage problems. The second part is intended to describe the important steps in the storage process that allow the conversion of digital data into genetic data, i.e. synthesis and sequencing operations. The last part is devoted to the benefits of DNA storage technology, which demonstrates the incredible storage capacity of thousands of gigabytes in a totally reliable way and can be a solution to store as much data as possible in a minimal space. Without forgetting the important challenges that prevent the spread of DNA technology, namely the high cost of DNA synthesis and the problem of rapid access.

Overview and research history of DNA storage

In 1974, (Watson & Crick, 1974) published one of the most fundamental articles in the history of biology in Nature, revealing the structure of DNA molecules as a carrier of genetic information. Since then, people have realized that biological genetic information is stored in a linear sequence of four bases in DNA. In just a decade, (Dong, et al., 2020) have proposed the concept of storing specific information in DNA. However, the concept was not realized because DNA synthesis and sequencing technology is still in its infancy.

In 1988, the artist (Davis, 1996) made the first tried to build a real DNA storage. He converted the pixel information from a "Microvenus" image into a 0-1 sequence arranged in 5 × 7 matrixes, where 1 represents a dark pixel and 0 represents a bright pixel. This information is then encoded in a DNA molecule of 28 pairs of bases (bp) long and inserted into E. coli. After restoration by DNA sequencing, the original image was successfully restored. In 1999, (Clelland, 1999) proposed to use a method based on "DNA micro-points," such as steganography, to store information in DNA molecules .Two years later, and in a similar way to coding amino acid sequences in DNA, (Bancroft, et al., 2001) proposed using DNA bases to directly encode English letters. (Dong, et al., 2020)

Church et al. managed to store up to 659KB of data in the DNA molecule, and the maximum amount of data stored before this work was less than 1KB. Goldman Sachs et al. are able to store even more, reaching 739KB. It should be noted that the data stored in both studies contain not only text, but also images, sounds, PDF files, etc., confirming that DNA can store a variety of data types.

The miracle solution to the data storage problem: synthetic DNA

(Vladek, 2019) mentioned that the production of data exceeds our current storage capacities, this is indeed a problem. So, in an effort to find a solution to this problem, researchers are experimenting with alternative storage methods such as DNA. It turns out that storing data in the form of DNA is something that has been known to do for several years. The problem was how to do it. Indeed, until now, the task was done by hand. But that's where Microsoft and the University of Washington come in. The American firm reveals to us that it has succeeded in automating the process.

Fig. 1: Nucleotides of DNA

The DNA Data Storage Technology in a Nutshell

(Bastien, 2019) presented the acronym DNA stands for Deoxyribonucleic Acid. It is a substance molecule found in the cells of all the living beings and which stores all genetic information. DNA contains tens of thousands of genes

designed to determine each of our characteristics, from our physical appearance to our personality. Thus, DNA is the natural equivalent of hard drives and other storage media. This is the reason why several researchers plan to store digital data there.

The principle of DNA storage is to encode binary data in DNA. For this, the individual bits (binary digits) are converted from 1 and 0 to the letters A, C, G and T. These letters represent the four main components of DNA: adenine, cytosine, guanine and thymine.

Modern DNA synthesizers can concatenate the four DNA-based nucleotides to form arbitrary-chain molecules of molecules. Each nucleotide (nt) in such a chain called oligo is considered to represent in principle 2 bits of digital data. Thus, the digital data can be stored in oligos, and even the stored data can be retrieved by reading the data representing oligos with DNA sequencers (Takahashi, et al., 2019)

Fig 2. DNA-based data storage

Steps of DNA storage

In this section, we present the basic steps to store and retrieve digital data to and from DNA storage.

In DNA, nucleotides are the small molecules that are fundamental building blocks of DNA. There are four types of nucleotides: adenine (A), cytosine (C), guanine (G) and thymine (T). The DNA strand is a DNA sequence of several nucleotides. Each DNA nucleotide (nt) refers to a 'base pair (bp)'. (Malithi, et al., 2020) presented the process of storing digital data in DNA is normally stored in binary forms. This means that we store the data with zeros and ones. The data on the hard drive is one and zeros, but DNA is made up of four basic components (A, C, G, T) instead of binary. Data can store in pairs instead of storing each 0 or 1 individually. As examples:

00 -> A

01 -> G

10 -> C

11 -> T

Once you have it, you can encrypt the data with artificial DNA.

Figure 3: Basic steps of DNA storage

DNA synthesis (writing)

The first step in storing digital data in DNA is called encoding, it consists of transforming digital data into DNA sequences. A program matches binary data to bases A, T, C, and G of DNA. Then this information travels to a machine

that synthesizes the DNA. When DNA is synthesized, it attaches to the surface of a solid support, so the next step is to use a solvent to rinse that surface. The solvent picks up the DNA and it ends up in a bottle containing a special liquid. (Vladek, 2019)

Theoretically, we can encode two digital bits per one nucleotide by the Quaternary system. We refer to the number of bits per base pair as encoding density. Due to the biochemical limitation and internal indexing overhead (i.e., offset and length), most existing works have the encoding densities smaller than 2.

Synthetic DNA strands can be stored in a single isolated pool, and the pool contains many different strands of DNA. In order to obtain random access from different strands of DNA in the pool, each strand of DNA must begin and end with primers to achieve the goal of Polymerase Chain Reaction (PCR (Bartlett & Stirling, 2003)). Use this pair of primers to copy the target DNA strand. The primers are short sequences of nucleic acids that provide a starting point and a final point for DNA synthesis. Usually, the length of the primer is between 18 and 25 bps.

DNA sequencing (reading)

We assume that the data has been synthesized and stored in a single pool/isolated DNA tube, which means that millions of different DNA strands are mixed into a single tube. The figure below shows the detailed process of sequencing DNA storage. To read the targeted DNA strands (the DNA strands synthesized with the same pair of primers), the first step is to extract a droplet from the DNA tube to amplify the target DNA strand by PCR. During PCR, a specific pair of primers is required as input, and the pair of primers is used to replicate the DNA strand. Usually, the PCR process takes several cycles to accumulate enough target DNA strands. After that, the DNA strand samples are sent to the sequencer for the sequencing process.

These sequenced DNA strands are then decoded in the original numerical data. During decoding, ECC (Error Correction Codes) codes are essential to ensure data integrity, as the sequencing process is also prone to errors. Finally, the internal index in the DNA strands will help identify the targeted DNA strands. In general, in ECC, the more redundancy there is, the more tolerant it will be to error. In a research study by (Li, et al., 2020) there are two approaches to adding redundancy for error correction purposes. One is to add ECC to a strand of DNA, and the other is, like the Redundant Array of Independent Disks (RAID) system, to store redundant data on DNA strands. Both achieve the same goal of recovering from errors in DNA strands.

Fig. 4: Detailed sequencing process.

A system design for DNA storage

The end-to-end system for DNA storage begins with bits of information (such as video files), which are coded, synthesized and stored in several strands of DNA oligonucleotides. The DNA strand must be sequenced, assembled and decoded to reconstruct the original source reliably. Figure 5 shows the full storage cycle. (Goela & Bolot, 2016) presented the system design for DNA storage includes the following components:

1. Data sources in pieces;
2. Encoding mechanism including all error correction codes and modulation from bits to nucleotides;
3. Synthesis of DNA from several strands of DNA;
4. PCR amplification of DNA pools;
5. DNA archival storage;
6. DNA sequencing;
7. Merging and assembling multiple DNA strands;
8. Demodulation and decoding of all codes for reliable recovery.

Fig 5. Block diagram of a DNA storage system

1. The advantages and challenges of DNA data storage medium

As mentioned above, global data is increasing exponentially. Traditional media cannot fully respond to Big Data's storage demand (De Silva & Ganegoda, 2016). DNA has potential benefits such as high density, high replication efficiency, long-term durability and long-term stability, so it can be used as a medium for digital data storage.

DNA at its theoretical maximum capacity, each nucleotide can encode about 2 bits. The entire data center created by IBM in 2011 has a data storage capacity of about 100 Po. However, because of its high density, DNA used as a data storage medium can store a large amount of data in a small size. The theoretical maximum of one gram of DNA can store about 200 Po of data, almost double that of the entire IBM data center (Akram, et al., 2018). In other words, (Sun, et al., 2019) are discovered that all the information stored in the world can be stored with a few kilograms of DNA, which is equivalent to a shoebox compared to the requirement of millions of large data storage centers for traditional media.

(Carroll, 2020) confirm that Digital storage media will soon become obsolete. The various storage media we know: floppy disks, CDs, DVDs, portable hard drives, USB sticks and cloud storage all have a limited lifespan. However, as long as there is biology and biologists, there will be people who will read genetic data.

The data-coded DNA medium is capable of long-term storage because of its high stability. DNA can survive for thousands of years in cold, dry and dark places. Even in a poorer environment, DNA has a half-life of up to a hundred years. DNA can remain stable at low or high temperatures, over a wide range of -800 to 800 degrees Celsius. DNA support can also protect data to a greater extent than traditional digital storage media. Although the amount of new data is increasing exponentially, most of it is archived for long-term preservation. This cold data will not be retrieved immediately or used frequently. Therefore, storing them on DNA media is simple, convenient and free (Sun, et al., 2019). Another advantage is that DNA is highly preserved. Natural DNA can replicate accurately with great efficiency and always with the basic principle of pairing (A with T, C with G). In this way, DNA support can strongly maintain data fidelity for a long time.

However, at present, the following disadvantages prevent widespread DNA implementation:

Based on its unique characteristics and compared to traditional media, DNA can be a potential and promising medium for digital data storage. However, there is still a long way to go before DNA is commercially available. The challenges we face exist in a variety of ways, including high cost, low throughput, limited access to data storage, DNA fragments of short synthetic trace, error rate in synthesis and sequencing.

(Monique, 2017) noted that the main disadvantage of DNA storage is that reading and writing DNA are fairly slow processes compared to other forms of data storage, and may not be appropriate when information is needed quickly. DNA storage can work best for archiving purposes. Storing genetic data is also more expensive than storing it on hard drives. The more you want your DNA to exist, the higher the cost.

Conclusion

Over the past ten years, technology has greatly developed and revolutionized society. Sometimes technological advances trigger the need to update existing tools. For Big Data, one of the obvious consequences is the need for new storage devices to adapt to data trends.

Synthetic DNA is an excellent choice for solving big data storage problems and becoming an urgent long-term storage medium for valuable digital data. If DNA molecules are stored in a dry, cold and dark environment, they must be strong enough to maintain integrity for at least thousands of years without the high cost of data migration such as data technology. In addition, DNA is tolerant of failures, it can keep two copies of the data to use one of the copies after the data is lost. In addition, DNA is a small and secure storage medium, it can store masses of data in a very small size and use secure methods to keep data away from unauthorized parts. Therefore, using these policies, the data can be provided as secure packaged data. Similarly, DNA can read files in parallel and at the same time. When encoding the data, and in all cases of error, the error is limited to this file and will not affect the remaining files. Therefore, this technique can be used for all types of files by making minor changes tailored to file types. In addition, these technologies can be used to store large amounts of data in a very small space with computational overload. Other strong arguments in favor of using DNA molecules to store digital data are that the possible storage density is about 5 PB per gram, DNA molecules can be easily copied at any time, and that there is in fact no risk of format obsolescence.

In this paper, we discussed DNA storage technology, namely the coding and decoding steps, its large storage capacity compared to traditional technologies, and the advantages and challenges of this biological storage model.

Discussion Topics

We have arrived at the end of this work but we cannot conclude without giving a glimpse of the future and an idea about new research. Researchers in chemistry, biochemistry and computer science at the University of Ghent, Belgium, have developed a revolutionary new data storage technique inspired by the idea of genetic storage of information. Powdered data storage could become a viable alternative and a more environmentally friendly technology.

Abstract

Rankings play an important role for any potential student who chooses a university. Given that, more and more young people are interested in investing in their education, wanting to pursue a rigorous specialization, being important to consider how students choose which university they will attend. Thus, not only students use international rankings, universities are showing a greater dependence on them. Thereby, in recent years there has been an increase in the interest of higher education institutions around the world, to be classified in international rankings.
Through this paper we aim to identify the impact that international rankings have on students' decision to choose a university. At the same time, we aim to identify the ways in which universities try to differentiate themselves in order to be as attractive as possible among students. Withal, we will detail the factors that influence the choice made by students. Finally, we will focus on the future perspective of performing a mathematical modelling to identify the share of influence of these factors on students' decisions for choosing the university.

Keywords: ranking, international, higher education, research, students

Introduction

Worldwide, interest for university rankings emerged in 2013, with the publication of the first editions of ARWU (Academic Ranking of World Universities) by Prof. Nian Cai Liu (Shanghai Jiao Tong University). This ranking is the result of the policy initiated by Jian Zemin in 1998, with the aim of propelling China among the major research players globally, by creating "world class universities" comparable to the best Western universities. The larger interest for this ranking has led to new global rankings, as well as the initiation in some countries (France, South Korea, Taiwan, India, etc.) of funding programs to stimulate the positioning of some universities among those of "world class" type.

A consequence of growing interest for university rankings at global level, is also given by the attention shown, including at government level, but also by the debate on the objectives to be pursued by education and research policies. Two visions can be identified here: "world class universities" or "word class systems"? Globally, it is noted that some negative effects generated by the concentration in some countries of the first option policies (the decline for the interest of academics in teaching, the encouragement of layering in university systems – generating social inequalities, the lower interest for social sciences and humanities, etc.). Simon Marginson, from Oxford University, notes that the transition in the second plan of teaching - learning process leads to an increase in the mass of those who form a low-quality academic system. For this reason, the UK government has created a „teaching excellence framework" which aims to improve the quality of education. The stratification of universities, with some being accepted in rankings as "world class universities", is stimulated by competition in the allocation of research funds.

In Romania, as of mid-2017, the ARUT Consortium (Romanian Alliance of Technical Universities) has been established, which aims the following aspects:

- Most of the rankings monitor a relatively small number of universities, those in Romania due to their presence in them especially by their size, the productivity per capita of our top 10 universities being relatively close;
- Critics of ranking systems argue, both in terms of content (unidimensionality, neglect of input-output structures of universities, etc.), and in terms of methodology (statistical robustness, elitism, dependence on the size of the institution, an attempt to impose a certain view of the role of universities, etc.);
- The allocation of resources on the basic of these is at least questionable decision, the priorities of the development are not automatically resolved by such a policy.

International Rankings

Currently, there are more than 20 international rankings worldwide. In order to have a comprehensive picture of university academic performance, we considered that a complex analysis of the most relevant such rankings is needed. Below we will present a list of the 11 international rankings that will be analysed below:

1. ARWU (Academic Ranking of World Universities - http://www.shanghairanking.com);
2. NTU Ranking (National Taiwan University Ranking – http://nturanking.lis.ntu.edu.tw);
3. THE (Times Higher Education World University Rankings - https://www.timeshighereducation.com/, UK);
4. CWTS Leiden Ranking (www.leidenranking.com, Holland, CWTS also involved in U-Multirank);
5. QS World University Rankings (https://www.topuniversities.com/university-rankings, UK);
6. URAP (University Ranking by Academic Performance, http://www.urapcenter.org/2018/, Turkey);

10. U-MULTIRANK (https://www.umultirank.org/, UE);
11. Google Scholar Citations (https://scholar.google.com/).

The indicators used to make the rankings and their weighting in the total score, differ from one ranking to another. Overall, they can be grouped in 4 fields of analysis: Learning environment, Quality of research, Transfer of knowledge and International orientation (including societal impact). Another important aspect to consider, as regards the assessment of the relevance of rankings, is related to the weight of indicators that depend on the size of the university, relative to those that are oriented at the performances per capita (per total academic staff, per number of students, etc.).

Table 1 presents the main performance indicators and their weighting over the fields of analysis, for the 11 rankings mentioned above.

Table 1: Performance indicators

Ranking	Learning environment	%	Research	%	Knowledge transfer	%	International orientation and societal impact	%
ARWU (Shanghai ranking)	- Nobel Prizes and equivalent; medals obtained by graduates; - Academic performance per capita;	**20**	- Teachers/researchers with Nobel prizes or equivalent medals by field; - Researchers with large numbers of citation; - Production of research;	**80**	-		-	
NTU (Taiwan)	-		- Research productivity; - Research impact; - Research excellence;	**100**	-		-	
CWTS Leiden (Holland)	-		- Publications in the most cited journals;	**25**	- The number and proportion of articles produced in collaboration with industry;	**25**	- International collaboration; - Gender diversity;	**50**
QS (GB)	- Reputation of graduates; - Total students/teachers' ratio; - Employer reputation;	**70**	- Research productivity; - Total number of citations; - Impact of the publications;	**20**	-		- International student ratio;	**10**
SCImago IR (Spain)	-		- Normalized impact; - High quality publications; - Excellence with leadership; - International collaboration; - Open access;	**50**	- Innovative knowledge; - Patents; - Technological impact;	**30**	- Altmetrics; - Inbound links; - Web size;	**20**
URAP (Turkey)	-		- Total number of articles; - Total citations of the articles published in a period of 4 years; - Total impact of articles; - Total impact of citations;	**85**	-		- International collaboration;	**15**
US News (USA)	-		- Global research reputation; - Normalized citation impact; - Conferences; - Books and publications; - Number of publications that are among the 10% most cited; - Percentage of total publications that are among the 10% most cited;	**90**	-		- International collaboration – relative to country; - International collaboration;	**10**
THE (GB)	- Reputation survey; - Staff-to-student ratio; - Doctorate-to-bachelor's ratio; - Doctorates-awarded-to-academic-staff ratio; - Institutional income;	**30**	- Reputation survey; - Research income; - Research productivity; - Citation (research influence);	**60**	- Industry income;	**5**	- Proportion of international students; - Proportion of international staff; - International collaboration;	**7,5**
UMultirank (EU)	- BA and MA graduation rate - Graduates in normative time - Relative BA and MA graduate unemployment - Innovative forms of teaching and assessment; - Student / staff ratio;	**25**	- External research income; - Research publications (absolute numbers); - Citation rate; - Top cited papers; - Interdisciplinary publications;	**25**	- Income from private sources; - Co-publications with industrial partners; - Publications cited in patents;	**25**	- Opportunities to study abroad; - Student mobility; - International joint publications; - International orientation of bachelor and master programmes;	**25**
CWUR (Emirates)	- Quality of education (awards, distinctions, international medals); - Alumni employment (executive positions); - Faculty members with academic distinctions;	**60**	- Total number of research papers; - Highly-quality publications; - Highly-cited research papers; - Influence of research;	**40**	-		-	
Google Scholar (USA)	-		- Highly-cited research papers of institution; - Performance of the top 10 ranked public profiles;	**100**	-		-	

The question is, in fact, why do we need these rankings? Why do most universities want to join as many such rankings as possible and get the best position in it?

The answer is a very simple one, namely, to increase the prestige of the university. What does this mean? The prestige of the university attracts as many high school students as possible, those who are the future students of the university.

What are universities doing to attract future students?

One of the priorities of any university, in line with its objectives, is to promote the educational offer among the general public, in order to attract as many talented high school students (future students) as possible, including from abroad. The aim is to increase the prestige, visibility and attractiveness of a higher education institution. Among the actions taken by universities to attract future students, the following can be listed:

1. Diversification of specializations

From the exact sciences, such as mathematics, physics, chemistry, to humanities, letters, history, sociology, etc., universities are increasingly seeking to expand their portfolio. The information is often found on university websites or on websites specifically dedicated to them.

2. Weekly newsletters

Another way to attract students is by making weekly newsletters. Therefore, universities transmit everything that happens within all faculties, both internally and internationally. They can include information on conferences, special events for students and high school students, admission, scientific communication sessions, special scholarships, competitions and conditions for participation, opportunities, workshops, etc.

3. Career fairs and internships

One of the most common ways to attract students is to organize career fairs and internships frequently. Their aim is to help students to fit more easily into the labour market. Each faculty has partnerships with different companies, which offer internship programs to all those interested, but at the same time also offers the freedom to choose from the existing offer on the market, as long as the specific of the studies program is respected.

4. Scholarships for exchanges of experience

They are found in most higher education institutions and offer students the opportunity to attend abroad courses, similar to those of the university they attend in the country, for a certain period of time. Thus, they gain international experience, practice a different education system and develop additional skills.

5. Attracting foreign students

Similar to students of the country who have the possibility to study abroad, for a certain period of time, foreign students can benefit from the same opportunity in our country. In addition to the Erasmus programs, they can also choose full study at a university as long as they take training courses in the language of that country, which take place before the actual studies begins. Therefore, foreign students are helped to integrate more easily, and the participation at courses will be facilitated.

6. The prestige of the university

As mentioned above, one of the most important criteria for increasing the prestige of a university, can be to occupy the highest position in the international rankings.
But is it enough that only the university should take certain steps to attract its future students?
In the following, the main factors influencing the student's decision will be presented as regards the choice of the university to follow.

How do students choose the faculty they want to follow?

In October 2020, the Romanian Centre for Urban and Regional Sociology (CURS) conducted a national opinion poll, in which it tried to identify the main decision-makers in choosing a university.

The sampling universe of the survey was based on stakeholders from pre-university education, namely: students, high-school students and teachers. The sample volume was 1.068 respondents. The sample type was probabilistic, multistage and stratified. The maximum margin of error across the entire sample was +/- 3%, at a 95% confidence level. The sample was validated based on the latest data from the National Institute of Statistics (INS) and the Education and Research Ministry (MEC) from Romania.

As shown in Figure 1, on the question „What are the main reasons why you would choose or recommend a form of study”, almost half of the respondents (42%) mentioned that "they have heard from others/knowns". Weighted by 36%, the following answer was "I studied/study there". "The quality", or as we call it in this article, the prestige of the institution, is the response provided by only 29% of respondents. At the opposite side, 10% and 9% are „good teachers” and „good students/graduates” respectively.

Figure 1

Another question answered by the 1,068 respondents was „Which people would you ask for advice on how to choose a form of education?". With almost similar weights of 38% and respectively 35%, responses were chosen, such as „knowns" and „friends". Other answers provided by survey participants were: „No one, I would choose what I want" – 26%, „teachers" – 24% and „parents" – 21%, and only 3% of respondents chose not to answer this question (Figure 2).

Figure 2

As can be seen from the images presented above, it is to be noted that there are several influence factors in the choice of a university, each of which has its weight. However, none of these factors must be excluded.

Factors that may influence the student in choosing the university

Looking at the above, a number of factors can be drawn which may influence, to a greater or lesser extent, the choice of an educational establishment by a high-school student:

Influence of colleagues

Most of the time, colleagues are one of the most important factors that can influence the choice of a university by a high school student. Often, they tend to follow the same studies that their older colleagues have followed.

Influence of parents

Another quite important factor in influencing the student's decision to choose a certain university is represented by parents. Most of the time, parents are thinking about the future that the child will have after completing his studies. They can also influence the profile that the young man can follow: technical, human, etc. The influence can also refer to the fact that in some cases, parents can make the decision in place of the student as regards the chosen university. It is also parents who can direct their children to study abroad or in the country.

Influence of teachers

Teachers can be another factor of influence for high school students. The problem is when looking at the studies that teachers in the school environment have followed, which are often humanists. Here, the decision can only be influenced in one way.

Influence of friends

Sometimes, in the student's decision, they weigh a lot the opinions of those close to us, as well as are the information taken from the social media. It is natural for prospective students to listen to the views of others, but it is important that the decision is made, individually, by each person, because this decision will greatly influence their career.

The prestige of the university

The prestige of the university is a quite important factor by which a student's decision can be influenced when choosing the university, he wants to follow. The academic, scientific and professional prestige of a university should be an emblematic of higher education. The students pursue the outstanding professionalism of the teaching staff, in the professional quality of many graduates; in the recognition of that school as being included in the elite echelon of international academic education through international rankings.

The opportunities after completion of studies

The opportunities that universities offer to students, both during and after their studies, can be important when a student chooses the university they want to follow. In this case, the examples can be numerous, ranging from the endowment of the university, the accommodation of the students and the employment opportunities after the completion of their studies, through the partnerships that the universities have with the representatives of the economic environment.

The Own Persuasions

The most important decisions are their own decisions. Even if these decisions can have a certain impact on high school students, both positive and negative, they also give them a certain responsibility. The more indecisive a teenager is about choosing the field of study, the more tempted those around them are to intervene with suggestions. Most of the time, students are wondering if the decision taken is the right one. The answer is simple: When they choose correctly for themselves, they feel clarified, motivated, determined, and doubts disappear.

The strategy of universities to attract students.

So, for universities to attract as many students as possible, the solution proposed by this study is to develop a strategy in this regard, namely, a "Promotion Strategy among students":

- the university to present its educational offer, updated with new trends and connected to the increasingly technological future;
- the university must maintain a permanent link with the local, national and even international press, through which it can communicate scientific achievements and research;
- the university must maintain a permanent connection with high school teachers, both by involving them in the various events organized by the university, and by constantly sending newsletters on the achievements of the university;
- universities must ensure that students' parents know the opportunities that are offered to graduates: scholarships, good conditions for courses, research opportunities, partnerships with businesses, finding a stable and well-paid job after graduation education;
- perhaps the most important aspect, the university must get in touch with the student, from the beginning of the pre-university cycle by: involvement in various events for them, sending newsletters on the achievements of the university, guidance to a profession that he likes, in line with what happens in everyday life: programming, robot development, medical device development, artificial intelligence.

At the same time, universities should take account the prospects for the future of education. In a study conducted by the Competitiveness Initiative Company (INACO) in 2018, the following were stated: there are still over 750 million illiterates in the world (10% of the Earth's population does not know how to write, read, calculate) ; only 6.7% of the population graduated from a university; the global learning market is huge ($ 107 billion in 2016); 20% of the planet's workforce (mostly women) work in Education; in the basic education of reading, writing and arithmetic are added to

programming languages; the determination of the European Union to give free access to all scientific papers and patents is important; virtual reality becomes a school technology; Open University, from the famous Massachusetts Institute of Technology (MIT) offers 2300 different Internet courses (STEM); great professors (like Abshok Goel of the Georgia Institute of Technology) use robots as assistants; education is personalized, a curriculum for each student; 60% of the children of the current generation will have professions and trades that do not yet exist; 60% of Earth's children also have a computer in the classroom where they study.

An agenda for the future of education was also proposed, presented in Figure 3:

Figure 3: The agenda of the future in education

Future Perspectives

In the future, we aim to make a mathematical modelling to identify the share of influence of these factors on students' decisions in choosing the university. Basically, there will be a mathematical formula that will return a percentage, for each decision factor. Mathematical modelling will be useful to any university in implementing the "Strategy to promote the educational offer among students".

Conclusions

Based on the analysed data in this paper, the rankings significantly help to maintain and build the institutional position and reputation. The fact that a certain higher education institution ranks as well as possible improves the chances of representing a potential choice of students.

At the same time, rankings - whether national or international - clearly have an impact on public opinion, institutional decision-making and individual choices.

Given the importance of higher education for the development of human capital, its cost for public funding and for individuals and their families, and the needs of business and industry; more and more young people are focusing on higher education, while universities provide a greater importance to national and international rankings.

However, universities consider that a good positioning in these rankings implies a better visibility and a greater impact, but also allows the possibility to identify the institution status, the level of development in compared to other universities around the world. Thus, universities choose to take a series of measures to promote among students, as well as promoting the educational offer to the general public in order to increase the prestige, visibility and attractiveness. In this sense, they diversify their specializations, make weekly newsletters, organize career fairs and internships, offer scholarships for exchanges of experience, pay extra attention to foreign students and focus on improving the prestige of the university.

Regarding the students, their decision is influenced by colleagues, parents, professors, friends, the prestige of the university, the opportunities after graduation and, last but not least, by their own beliefs.

Therefore, this study proposes the development of a strategy in order to attract students, by promoting among them the educational offer, updated with new trends. However, universities should maintain a continuous contact with the press and high school teachers, both through their involvement in various events, and communicating scientific achievements and research conducted. Finally, universities should ensure that students' parents know the opportunities that it offers to graduates (study scholarships, good conditions for courses, research opportunities, etc.). They also should keep close contact with students, since the beginning of the pre-university cycle, by getting involved in various events for them, taking account the perspectives of the educational future.

An Entrepreneurial Approach to Government Employee Family Welfare in Developing Countries
KPK (Pakistan) Police Employee Wellbeing
Gratifying the Distinguished Services of Police Employees

Rahatullah Muhammad Khan

Effat University – Jeddah – Saudi Arabia
mkhan@effatuniversity.edu.sa

Abstract

Developing countries like Pakistan face challenges of payment of sufficient benefits at the superannuation to their government employees. Anticipating this the employees resort to unfair practices in an endeavour to safeguard own and family's future post retirement. This paper identifies the problem and proposes a solution whereby the government has minimal resource investment and yet their employees and families can generate revenues on continual basis through productive family concept. The model is proposed for Khyber Pukhtoon Khwa (KPK) province police department initially and can be replicated for other government departments and countries. The concept can generate a number of jobs and raise the economic conditions at micro levels thus contributing nationally.

Keywords: Police Employee Wellbeing; Family Welfare; Entrepreneurship; Productive Families

Introduction

Homo sapiens are constantly involved in a struggle to achieve personal wellbeing. However, as the times passed the wellbeing landscape evolved as well and realizing the personal wellbeing became dependent on a number of factors. The economic wellbeing cannot be achieved unless the humans are physically and biological strong and able to perform tasks that can produce wealth. Moreover, the protection and security are required in order to achieve the social and psychological comfort and realize the personal comfort and wellbeing.

Every year hundreds of police force personnel die performing their routine daily life to protect, help and shield society from known and unknown dangers. More than 1400 brave police employees have laid their lives in last 10 years in KPK (Geo News 2018). This requires huge recognition and all steps should be taken to offer gratitude for their efforts and services rendered. Humans can act deviously when their wellbeing is not taken care of and yet it is expected of them to perform in scrupulous and dedicated manner.

The police forces around the world enjoy economic wellbeing and security during and after superannuation and can be related to people working in other fields and jobs (Sulaiman 2018). How can they are expected to work longer hours, earn comparatively less money, have huge powers and yet continually ponder on his/her family future during and post retirement. The police image is unjustifiably tarnished, efforts and services ignored and blamed for the debauched corrupt economic practices.

A department and its personnel can be held responsible and accountable if the welfare of the employee and his/her family, during service, post retirement and upon demise is ensured and secured. However, if the employee is unsure of their economic future, they will act opportunistically. Therefore, it is the responsibility of the state. Though, Pakistan which ranks 171 among 200 countries in GDP, PPP per person; according to ciafactbook (2020); its government may not be able to provide an answer.

A strategy is proposed to be implemented at the KPK police department through entrepreneurial initiatives for long term sustainable welfare.

Police Force of KPK and its Employee Welfare

The KPK province employs more than 83, 000 people. According to Pakistan Bureau of Statistics (2020) average household size in KPK is 6.31 persons. It will make more than 0.523 million people associated and requiring welfare programs every year. Similarly, if 3% of the employees retire; on same ratio it would mean 2490 retiring personnel *

Cite this Article as: Rahatullah, Muhammad Khan "An Entrepreneurial Approach to Government Employee Family Welfare in Developing Countries KPK (Pakistan) Police Employee Wellbeing Gratifying the Distinguished Services of Police Employees" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

6.31 and that means more than 15,700 people looking for a means of income every year with very little regular income coming to the household. These are daunting numbers for an economically frail country and then even more for a shoddier province. The retirement benefits including the gratuity, provident fund etc. and the pension are also not enough to run a household with current inflation rates. This means a denial to a decent living.

Therefore, it warrants and requires an innovative approach to help the department realize welfare schemes for employees post retirement in particular and during the service in general. This will help release the stress and motivate the employees work more productively, transparently in just and fair manner because economic woes lead the humans to act unethically and compromise fairness.

Mehsud (2018) KPK police Recruitment Strategic & Implementation Plan 2018-2023 reveals core values but does not identify that it values "Employee welfare post retirement". The SWOT analysis in the plan reveals the threat of losing donors exist. This means the additional restraints and burdens may fall on the department in future. The department also has developed a commendable strategy in recent years for employees who embrace martyrdom. These welfare plans include Shuhada package and priority in recruitment at all ranks on basis of their qualification and age. However, it is evident that the plan falls short of developing and implementing a comprehensive employee welfare plan post superannuation.

Proposal, its Aims and objectives

It seems pertinent to devise and implement a project which can help eradicate the social pressures and economic insecurities from the police department employees. This would help them realize their potential and perform optimally in the best interest of the country, the masses and the province.

In order for the project to catalyse the financial security, develop productive families and release social and economic pressures from its employees two models based on entrepreneurial philosophy and principles is being presented.

Factors determining quality of life and wellbeing

The project would:

- Assist the employees achieve financial security for the employees during and after their service.
- Create jobs for family members of the police department employees in particular and others in general.
- Develop new sustainable tiers in the economic fabric and social of the province
- Release social and economic pressures from the employees and their families.
- Bring sustainability to welfare schemes of the police department.
- Help raise the performance bar of the employees through its outcomes and
- Raise the confidence of the general public in the department.

It is the opportune time for this police welfare program grounded in surface realities, requiring little or no governmental funding with least involvement of police personnel yet help the department achieve social and economic wellbeing for its employees, achieve its targets of candid work environment, raise the public confidence and raise performance bar.

The proposed models of KPK Police Employee Welfare

There could be two models built upon entrepreneurship, i.e. Entrepreneurial and Skill Training Model and Hybrid Entrepreneurial Business Model to nurturing KPK police productive families. Both are discussed below. These proposals once implemented would allay the economic woes and fears of the police department employees and they would be able to work and perform better.

For both models the department / provincial government will provide legal and protective umbrella by taking the policy decision to implement the police employee family welfare initiative and ensure all such necessary support.

Both the models recommend development through accelerator / incubator which could be established at each district level or the province districts could be divided in 10-11 zones of 3 or 4 districts depending upon the population size of the police force employees, market size and others.

Entrepreneurial and Skill Development – Productive Families

This model of productive KPK police employees' welfare hinges upon entrepreneurial and skills development of eligible employee family members. There would be two options available, first will be through the entrepreneurship accelerator and second through standalone registered entrepreneurs (employee family members who already possess necessary skills and experience). This documents identifies two strategies. Either one or both could be implemented concurrently. These plans are based on development of local ecosystems and support infrastructure at little or no cost to police department / provincial government.

The accelerator / incubator at each district level will provide holistic assistance and would identify the eligible members of the employee family and develop their entrepreneurial, business and other skills. These skills will aim to enhance the potential entrepreneur's ability to understand the latest concepts in the business, understand the importance of customer satisfaction, and develop skills to maintain the accounting books, advance and implement marketing and promotion strategies at district, provincial and or the national levels. These trained family members with the help of revolving fund, investments or funding, a business plan (based on the individual education, experience, market size for proposed product and or service and aptitude) would be established. Such developed entrepreneur would be assisted in developing business plan, feasibility study, business, operations and marketing training etc. The accelerator/incubator owners will share profits and losses with family member entrepreneurs.

Nurturing KPK Police Productive Families—Entrepreneurial and Skill Training Model

The police department would help secure suitable outlets at provincial headquarters and in major cities to sell the products of productive families. These outlets would be called "Police Employee Family Welfare Shops" The profits would be shared between the entrepreneurs, police welfare unit and the shops owners.

Hybrid Entrepreneurial Business Model - Productive Families

The program will be carried out at district level through identified and purposefully enlisted entrepreneurs and a musharaka company would be established. This will help the groomed / mentored and coached entrepreneurs sell their produce in the market and reap monthly salaries to produce products / services for the musharaka company.

The district based entrepreneurship unit performs the tasks through entrepreneurs and a musharaka company that benefits from the services of an accelerator / incubator. The selection of potential entrepreneur for accelerator or incubator would depend upon the applicant personality characteristics, aptitude and business requirements. In order to make the arrangement economically and financially attractive the unit may seek collaboration with an existing musharaka company or establish a new and bring sustainability and revenue.

Fostering KPK Police Productive Families—Hybrid Entrepreneurial Business Model

In this arrangement the accelerator / incubator would provide skill training to the potential entrepreneur. Upon completion of the training the unit would provide the raw materials to the entrepreneurs to produce the product / service at a predetermined price per unit. In order to provide increased benefit to the family members / entrepreneurs the accelerator / incubator would provide extra raw materials. For example, if 100 units of a product requires 10 kilograms of raw materials, the entrepreneur would be provided with 13 kilograms of the raw materials. This would give the entrepreneur ability to produce extra and sell that to either the "Police Employee Family Welfare Shops" or in the market or to the musharaka company / welfare unit. The unit would also pay a certain amount to the entrepreneur for producing the number of units they do.

Funding Options

Funding would be required for these start-ups / entrepreneurs start the project with minimal stress. Commonly start-ups are compelled to pay interest, equity / shareholding, be at the mercy of institutions or wealthy investors for financial resources. They also at times face massive difficulties of the bureaucratic and banking restrictions and delays.

Funding requirement could also be served through crowdfunding. A platform for such funding could be established at provincial level.

Second alternative is that depending upon the funding available an endowment fund in the name of "Police Employee Family Welfare Fund" could be established. This fund would be managed at the provincial level and each district unit would be eligible for a certain amount based on the number of potential entrepreneurs from employee families, size of business (investment size) and total number of beneficiaries in the district. Part of the revenues would be distributed to the needy families and remaining inducted back in the fund for future use and sustainability.

Conclusions

The implementation of the plan would provide numerous economic, social and financial benefits as identified below.

- Community – social impact
- Stakeholder impact
- Relief to the employees from economic woes
- A new approach to development and acquiring welfare at no or little cost
- Women empowerment
- Productive families development
- Contribution to overall police employee welfare
- Assistance in long term economic and financial sustainability of the department
- Reduction in overall provincial unemployment rates
- Economic uplift of financially weaker section of society
- Peace of mind for the police department employees
- Security of financial future of the police department employees

With little or no income this project can play a vital role in the police department welfare which can be replicated in other provinces of the country. The plans will require a suitable space provided by the department at the district police facilities and properties.

Maternity and Parental Leave: Rights and Obligations of Female Employees According to the Slovak Legislation

Marian Hortváth JUDR., PHDR., PHD.

JANKO JESENSKY FACULTY OF LAW DANUBIUS UNIVERSITY, RICHTEROVA SQ. 1171
925 21 SLÁDKOVIČOVO, SLOVAK REPUBLIC
E-MAIL: MARIAN.HORVATH@VSDANUBIUS.SK

Abstract

Maternity and parental leave are two separate legal concepts of the Slovak legislation. The labour law as well as the social security law establish the legal framework in this area. With this regards Labour Code (Act no. 311/2001 Coll.) grants an employee - a woman the right to maternity leave and parental leave in connection with the childcare; whereas an employee - a man has the right to parental leave in connection with the childcare. Both institutes are linked not only to rights but to obligations as well. This article focuses on the rights and obligations of female employees rooting from these two legal concepts.

Keywords*:* maternity leave, parental leave, employee, woman, care of the child.

Introduction

Maternity and parental leave are two separate legal concepts of the Slovak legislation. The labour law as well as the social security law establish the legislation in this area. De lege lata grants the female employee (mother) the right to maternity leave and parental leave in connection with the child care; whereas the male employee (father) has the right to parental leave in connection with the child care. Both institutes are linked not only to rights but to obligations as well. Our article focuses on the rights and obligations rooting out from these two legal concepts.

Legal framework of maternity and parental leave

The legal framework of maternity leave and parental leave is set mainly by the Act no. 311/2001 Coll. – Labour Code (hereinafter referred to as the Labour Code). The legal definition of maternity and parental leave is provided in provisions in § 166 - 169 of the Labour Code. According to § 166 (1) in connection with the childbirth and care for a new born child, the woman shall be entitled to maternity leave for the duration of 34 weeks. A lone woman shall be entitled to maternity leave for the duration of 37 weeks, and a woman who gave birth to two or more children simultaneously shall be entitled to maternity leave for the duration of 43 weeks. In connection with the care for a new born child, the man shall also be entitled to parental leave from the birth of the child, in the same scope, provided he cares for the new born child.

The above mentioned indicates that the Labour Code provides different lengths of maternity leave depending on the social status of the mother (married vs. single) as well as on the number of new born children. Treľová and Matlák (2018) advocate the prolonged maternity for both groups of mothers and with regards to lone mothers they state "we assume that prolonged maternity leave for lone mothers is legitimate. Respecting the fact that loneliness is a social and psychological phenomena, as far as social security in concerned single mothers shall treated with an increased attention."

The Labour Code does not involve any specific definition of neither the mother nor the father; therefore, the legal definition from the civil law shall be applied. According to § 82 (1) of the Act no. 36/2005 Coll. on family and on amendment of some other acts (hereinafter referred to as the Family Act) mother is defined as the woman that gave birth to a child (*mater semper certa est)*. The legal definition of fatherhood is set in § 84 of the Family Act. Since a woman commences its maternity leave before becoming a mother i.e. prior she gives birth to a child, it is important to mention that the § 40 (6) Labour Code provides the legal definition of a pregnant employee as an employee who has informed her employer in writing about her condition and has provided medical confirmation about it. Regarding

Cite this Article as: Marian Hortváth " Maternity and Parental Leave: Rights and Obligations of Female Employees According to the Slovak Legislation" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

this Treľova and Procházková (2019) draws attention that "the status of a pregnant employee can only be obtained if the woman informs the employer about her condition in writing and her pregnancy is confirmed by a specialist. The pregnancy certificate (booklet) is normally used as medical confirmation. It is issued for the pregnant woman by the doctor usually between the tenth and twelfth week of pregnancy. If these conditions are not met the employee is not seen as pregnant and such woman has the status of a "regular" employee."

Slovak legislation grants parents the right to take care of their children and raise them as well as children have the right to parental upbringing and care. Parental rights concerning the care and upbringing of children are reflected in the labour law in the concept of maternity and parental leave granted for the mother and parental leave granted for the father. "The aim of the legal concept of maternity and parental leave is to guarantee increased protection for the woman (mother) and man (father) in employment relationship established by employment contract. With this regards the Labour Code obliges the employer to respect the personal obstacle to work on the side of the employee (giving birth and taking care of the new born child." (Treľová 2019)

In comparison the author states that regarding the right of employee – man (father) that though Slovakia has no official "paternity leave", its legislation allows men to stay home with their child for 28 weeks until the child reaches three years old, while receiving the maternity benefit.

Rights of mother during maternity and parental leave

Maternity and parental leave as legal concepts of the Slovak legislation aim on one hand to protect the female employee (mother) in employment relationships established by employment contract during an explicitly set period of time before and after the birth of her child (according with Szarková and Krásna, 2016) and on the other hand provide special allowances i.e. childbirth allowances, maternity benefit and child allowances.

With regards to the beginning of maternity leave one must note that at least one month prior to taking the maternity leave, the woman shall notify the employer in writing of the expected date of taking the maternity leave, the expected date of interrupting, terminating the maternity leave and any change concerning the commencement, interruption and termination of the maternity leave.

In Slovakia generally, a woman usually starts her maternity leave at the beginning of the sixth week prior to the expected day of childbirth, however, at the beginning of the eighth week prior to such a day at the earliest. On the other hand, paternity leave as the analogical right guaranteed for employee - man (father) is not granted before the birth of the child.

From the perspective of employee protection, the mother is subject to protective period during maternity leave, during which she may not be dismissed, and her employer may not terminate her employment immediately. At the same time, the maternity leave is considered to be a period of work and therefore it gives the mother entitlement to regular leave, which she can draw after returning to work.

A woman shall commence her maternity leave in the eighth week at the earliest, however, in the sixth week as the latest prior to the expected day of the childbirth. If a woman is registered with the Office for Labour, Social Affairs and Family (hereinafter referred to as the "Labour Office"), she shall submit a form certified by the physician to the Labour Office before taking her maternity leave. If the woman is employed, she shall hand over the form confirmed by the physician to the employer. In accordance with the provisions in §231, para 1 d) of Act no. 461/2003 Coll. of laws concerning the social insurance (herein after referred to as the "Social Insurance Act") the employer shall subsequently notify the branch office of the Social Insurance Agency of the commencement of the maternity leave within 8 days from the beginning of the maternity leave. The woman shall also notify the health insurance company of the maternity leave. If the woman is employed, the employer shall carry out this obligation; in other cases she shall do it herself.

The childbirth gives mother the entitlement to childbirth allowance. The Act no. 383/2001 Coll. of laws concerning the childbirth allowance and multiple birth allowance regulates provision of this allowance. Entitlement to this allowance shall arise for the child's mother or the child's father if the child has been taken into his custody by a court or if the mother died. The condition for entitlement is the birth of a child and the permanent residence of the entitled person in the territory of Slovakia. It is important to underline that *de lege lata* grants different amount of childbirth allowances depending in case of multiple birth as well as different amount of childbirth allowances for the fourth or higher child that is born. The amount of childbirth allowances is set on § 4 (1) of the Act no. 383/2001 Coll. of laws concerning the childbirth allowance and multiple birth allowance regulates provision of this allowance; whereas the allowance shall:

- amount to €829.86 for the single birth of the first to third child where such child survives at least 28 days;
- amount to €151.37 for every fourth or higher child that is born or for the first to the third child if such a child does not survive for at least 28 days;
- for birth of two or more children if at least two of them survived 28 days the sum of €829.86 shall increase by € 75.69 per each child who survived 28 days or
- amount to € 110.36 in case of multiple birth.

It is important to state that childbirth allowance is not preconditioned by any existing or previously existed employment relationship the only relevant precondition is the permanent residence of the entitled person in the territory of the Slovak republic.

In addition to aforementioned allowance a parent is entitled to child allowance pursuant to Act no. 600/2003 Coll. of laws concerning the child allowance amounting to € 23.52 or possibly the supplement to the child allowance amounting to € 11.02. A parent caring for a dependent child is primarily entitled to child allowance. The sum of the parent´s income is irrelevant. Should the child be not cared for by the parent, the law stipulates exactly who is entitled to. The first condition, however, is that a parent or other person shall take care of the child. Both the parent and the child shall have a permanent or at least temporary residence in Slovakia. The following conditions shall also be met in order to request the supplement:

- to be an old-age pensioner, beneficiary of the early old-age pension, invalidity pension due to reduced capacity to perform economic activity by 70%, service pensioner or any other beneficiary of the pension defined by law,
- not to be gainfully employed nor any other physical person who could claim the tax bonus for the child,
- in case of claiming the allowance and requesting the supplement, it is not possible to grant the tax bonus for the child.

Furthermore, the Slovak social security entitles mothers for a maternity benefit in case the mother fulfils the obligatory conditions set by the Social Insurance Act. The provisions in § 48-53 of the Social Insurance Act regulates mother´s entitlement to the maternity benefit during the maternity leave. The mother is entitled to maternity benefit if she is insured against sickness at the time when the right arises and she had sickness insurance for at least 270 days during last two years before giving birth. Entitlement to maternity benefit arises from the beginning of the sixth week before the expected date of birth designated by the doctor, at the earliest from the beginning of the eighth week before that day and, if she gave birth earlier, then from the date of birth. The mother is entitled to maternity benefit for the period of 34 weeks; in case of taking care for two or more children it will be for 43 weeks or in case of a single mother it shall be for 37 weeks. The amount of maternity benefits depends from her previous income; it is defined as 65% of the assessment basis laid down in §55 or §57 of the Social Insurance This amount. The amount of maternity benefit is calculated from the mother's income in the calendar year preceding the year in which the right to maternity benefit arose. Act. It is important to note that legislation caps the level of maternity benefit. The maximum daily assessment basis shall be € 39.6987. With regards to maternity benefit one shall bear in mind that unless the mother is entitled to maternity benefit, she shall be entitled to parental allowance.

The Slovak legislation also recognizes that there is a group of mothers which returns to the work before the maternity leave ends. Mother that decides to work during her maternity leave is entitled to childcare allowance. The provisions of this allowances is laid down in Act no. 561/2008 Coll. of laws concerning the childcare allowance define the aforementioned allowance. The allowance is paid up to the age of three of a child or up to the age of six of a child with a long-term unfavourable health condition. If the mother proves the expenses for childcare, she will be provided with a contribution amounting to expenses, up to the amount of € 230; unless she proves the amount of expenses, the amount shall be € 41.10.

Situation of the mother after maternity leave

Once the maternity leave terminates mother has basically two option; indeed the mother may return to work or draw the parental leave. The provisions of parental leave are set in § 166 - 169 of the Labour Code. The parental leave belongs to mother until the day when the child reaches the age of three. If this concerns a child with long-term serious health disability requiring exceptional care, the employer shall provide a woman with the parental leave until the child is six. The aforementioned leave shall be granted to the extent requested by parent, however 1 month being the minimum period. An application addressed to the employer shall be the condition for granting parental leave. The law does not stipulate that the application must be in writing; however, for reasons of legal certainty in any subsequent disputes, it is appropriate to submit the application in writing.

It is worthwhile to note that the parent shall notify the employer in writing at least one month before the start of the parental leave of the expected date of the commencement of the parental leave, the expected date of interruption and end of the parental leave and any change concerning the commencement, interruption and end of the parental leave (similar to maternity leave). Since the respective Office for Labour, Social Affairs and Family pays the parental benefit, the mother shall fill in the relevant forms before the end of the maternity leave and shall have them confirmed at the branch office of the Social Insurance Agency and then shall deliver them together with the copy of the child´s birth certificate to the Office for Labour, Social Affairs and Family. In addition, the mother shall also notify the health insurance company of the change related to the commencement of the parental leave. During parental leave, the mother is entitled to a parental allowance of EUR 270 (EUR 370 if she previously received maternity leave); if the mother cares for two or more children born at the same time, the parental allowance is increased by 25% for each child born at the same time. When receiving parental allowance, "participation in social insurance relationships is not examined and income is not tested. At the same time, the fact whether the entitled person is or is not economically active is not decisive either" (Treľová 2016).

Regarding the rights of mother, one must emphasize that during parental leave the mother is subject to protective period, during which she may not be dismissed and her employer may not terminate her employment immediately. The parental leave is also considered to be a period of work therefore it gives the mother entitlement to holidays, which she can draw after returning to work.

Situation of the mother after parental leave

After parental leave, three or six years after childbirth, mother can take various decisions concerning work; indeed she can return to work; she can agree with the employer on unpaid leave; she can remain unemployed, or she can become a self-employed person. In the first case, the mother shall notify the employer of the end of the parental leave, and also report the change to the Social Insurance Agency and the health insurance company. If the mother agrees with the employer on unpaid leave, she must reckon with the fact that she will not receive any social benefits. If she decides to terminate her employment with the employer, she shall register with the relevant Office for Labour, Social Affairs and Family within 7 days. If she becomes the self-employed person, she shall notify the Social Insurance Agency and the health insurance company of such a change.

Special situation occurs where the mother becomes pregnant during parental leave and goes on maternity leave after the end of the parental leave. In such a case she is entitled to maternity benefit only if she had her sickness insurance for at least 270 days during last two years before giving birth. For the purposes of calculating maternity benefit, the period of the maternity leave and parental leave are also considered to be the period during which mother has sickness insurance therefore the mother is entitled to maternity benefit. The mother shall notify the employer of the transition to the maternal leave.

Conclusions

Slovak legislation grants parents the right to take care of their children and raise them as well as children have the right to parental upbringing and care (Gabrhelová and Čepelová, 2019). Treľova and Kulhánek (2019) came to the general conclusion that "it is essential to ensure effective support for reconciling work and family life for parents of young children, especially for mothers who are more often associated with childcare."

With regards to childbirth and upbringing of children the Slovak legislation provides specific rights to female employees; indeed there are to specific legal concepts: maternity and parental leave. Maternity and parental leave as legal concepts of the Slovak legislation aim on one hand to protect the female employee (mother) in employment relationships established by employment contract during an explicitly set period of time before and after the birth of her child and on the other hand provide special allowances i.e. childbirth allowances, maternity benefit and child allowances.

The Labour Code provides different lengths of maternity leave (34, 37, 43 weeks) depending on the social status of the mother (married vs. single) as well as on the number of new born children. After maternity leave de lege late entitles mother for parental leave. Once the parental leave is terminated, three or six years after childbirth, mother can take various decisions concerning work; indeed she can return to work; she can agree with the employer on unpaid leave; she can remain unemployed, or she can become a self-employed person.

During maternity leave mother is entitled, after compelling with legal conditions, for maternity benefit; unless the mother is entitled to maternity benefit, she shall be entitled to parental allowance. During parental leave the mother is entitled to the parental allowance.

Analysis of The Impact of Telemedicine on Health Care: A Review of The Scientific Literature From 2015-2020

Michael Castillon-Herrera

Universidad Autónoma del Perú, Lima, Perú
mcastillonh@autonoma.edu.pe

Michael Cabanillas-Carbonell

Universidad Autónoma del Perú, Lima, Perú
mcabanillas@ieee.org

Abstract

Currently, people with reduced mobility, with some physical disability or people who are in remote areas, as well as in a situation of confinement, cannot receive medical attention in person. These problems can be solved through telemedicine. This research is a systematic review of the scientific literature and aims to determine the criteria to be considered for the analysis of the impact of telemedicine in medical care. For which 50 articles were systematized, collected from the databases of the IEEE Xplore, Scopus, Science Direct, Scielo. Having very favorable results about the impact of telemedicine in medical care and in the different fields related to medicine.

Keywords: "impact of telemedicine", "medical assistance", "telemedicine system".

Introduction

Currently the severe acute respiratory syndrome coronavirus (SARS-CoV-2) and the disease it causes, (COVID-19), are causing a rapid and tragic emergency worldwide. This is leading to a restructuring of health systems in several countries around the world, due to the need to devote significant medical resources to the care of critically ill patients with, which also has important implications for other medical disciplines not related to the virus.(Novara *et al.*, 2020). At a global level, telemedicine continues to be imposed both in the first level countries, as well as in countries that are progressively improving their development. Therefore, experts agree that telemedicine will improve medical care in these countries(Fong, Fong and Hong, 2005). But what is telemedicine? telemedicine is defined as the provision of health care services in which distance is a critical factor, carried out by professionals who use information and communication technologies to exchange diagnostic data in order to improve the health of individuals and the communities in which they live, according to the OMS (1998)(Shojaei *et al.*, 2020).

The origin of telemedicine is linked to the origin of telecommunications in the late nineteenth century, with the invention of the telegraph, where it was first used in the U.S. Civil War, which served to report on wounded, killed in combat, even exchanging information with a doctor to save the life of a wounded. And with the advent of the Internet in 1990 the term telemedicine progressively evolved into what we know today(Suh et al., 2012). In the United Kingdom, the Queen Victoria Hospital, in 1988, used wireless technology via satellite and fiber optics, for telemedicine applications. As in the United States, one of the factors that have most influenced the development of these systems is the high cost of health care for its inhabitants(Setiawan, Syamsudin and Ruhiyat, 2018). In Peru, out of the 11,000 health facilities in the country, only 3% are part of the network of the Ministry of Health, for telemedicine the goal is to achieve 10% each year end, in addition Essalud has the national center of telemedicine for its network of services. However, in the sub public sector very few have these services while, in the private sector, there are advances in several clinics(Vidal-Alaball et al., 2019).

Advances in wireless bandwidth and now also access networks that are intercepted by a variety of technological devices, this makes it possible to implement telemedicine applications in any country (Fong, Fong and Hong, 2005). According to a study by Global Market Insight, the 19.2% annual growth rate will be driven by the development of telecommunications, government initiatives to provide health services to the population that has limited or no access to health services, and the increasing integration of the health and IT sectors(Mohammed *et al.*, 2014). This makes it even more relevant considering that the current situation, with a decreasing level of emergency, will probably affect

our activities for several months and will modify the organization of our hospitals, making telehealth more recognized and used in the very near future (Koesoema *et al.*, 2017).

Methodology

For the present document, a process of systematic revision of literature was carried out, which was consulted in different databases, where it was possible to discard articles that did not fulfill the requirements for this study. The search was obtained with key words, which were explained in section B, according to the determined scientific orientation.

A. Research Questions

The research questions used were the following:

RQ1. What are the best techniques and strategies for the implementation of telemedicine?
RQ2. Which are the medical specialties most benefited by telemedicine?

Figure1: Prisma Diagram Methodology

B. Search Strategies and Processes

The research considered the field of action of the issues raised, taking into account the following key words: "impact of telemedicine" or "medical assistance" or "telemedicine system". In addition, in order to answer the research questions, a systematization of articles published in the following databases was carried out: IEEE Xplore, Science Direct, Scopus and Scielo. In the end we were left with 50 articles, considering from 2015-2020

C. Inclusion and Exclusion Criteria

For the study, the following exclusion and inclusion criteria were applied as shown in the following table.

TABLE 1: TABLE OF CRITERIA

CRITERIA		
Inclusion	I1	Articles were found in English.
	I2	The publication years are 2015-2020.
	I3	Articles with the purpose of answering research questions.

Exclusion	E1	Some items do not apply to engineering or medical areas.
	E2	There were articles whose publication year was prior to 2015.
	E3	Some articles that are not very related to telemedicine.
	E4	Those articles whose conclusions do not provide relevant evidence for the present study.

Results

Research results are oriented to research findings. The process of analysis that was carried out was the following.

A. *Extracted and Analyzed Articles*

We analyzed 83 articles found in the databases related to the topic, of which we discarded 5 articles that were repeated or had very similar topics. After reading the articles, 78 articles were selected, excluding 28 according to the exclusion criteria and that did not contribute to the answers to the research questions. Obtaining 50 articles for the systematic review

Figure2: Article selection flowchart

The 50 selected articles met the established inclusion criteria. Now we will make the final count of articles per database: IEEE Xplore, 12 articles; Science Direct, 19 articles; Scopus, 17 articles and Scielo, 2 articles.

B. *Chloropletic Mapping of Databases*

Figure3: Coropletic map of the databases

The coropletic map is used to compare values and display categories in various geographical regions worldwide. In this graph we can appreciate the geographical location of the countries of origin of the databases found.

C. *Distribution of the quantity of BD found*

Figure 4: Distribution of total databases

In the following graph you can see the distribution of the total amount of the databases, where the largest amount of articles that were left for systematization belong to Science Direct, with 38% of the total and the smallest amount is 4% belonging to the Scielo database.

D. *Number of Items per Year*

Figure 5: Number of items per year

Clearly it could be seen that the year with the most publications was 2019 with 20, and 2016 was the year with the least number of publications with only 3.

E. *Number of Items per Year and Continent*

Figure 6: Number of items per year and continent

In the present graph you can appreciate the amount of articles published per year and to the continent that correspond. It is clear that the continent that obtained more publications was North America, besides being in 2019, the year with more publications corresponding to that continent.

F. Number of Articles by Continent and Categories

Figure7: Number of items per continent and category

In this graph you can see that we have a large number of articles in the category: Application of telemedicine, which belong to North America and is also the continent with the largest number of articles.

Table 4: Classification of Articles According to Research Questions

ARTICLES	RESULTS
(Vidal-Alaball *et al.*, 2019); (Garichev *et al.*, 2019); (Nadar *et al.*, 2019).	These articles argue that to implement telemedicine requires, apart from having the necessary technological requirements, is to have a structured and solid project planning as a fundamental basis for making telemedicine a reality.
(Binder *et al.*, 2018); (Setiawan, Syamsudin and Ruhiyat, 2018).	These articles tell us that, through a broadband program of the Ministry of Communications and Information Technology, they managed to implement telemedicine in Latin American countries.
(Lenney, 2018); (Kindle *et al.*, 2019); (Castaneda and Ellimoottil, 2020).	Medical specialties most benefited by telemedicine

In the table shown you can see the classification of articles, according to the two research questions, thus answering the first question, which will be detailed in the discussion section.

Medical specialties most benefited and with greatest application in telemedicine

Figure 10: Medical specialties most benefited by telemedicine

In the following graph we can clearly see which are the medical specialties most benefited by telemedicine, highlighting dermatology.

Discussion

In this systematic review research, the study of which would be the best techniques and strategies to implement telemedicine was determined, as well as knowing which medical specialties would benefit most from the use of this technology. As indicated in Figure 8, we can appreciate a greater presence of results in the continents of Europe and North America, which in a certain way shows us that in these continents they have more technology and better management to implement telemedicine, as well as applications and research with other medical specialties, compared to the majority of South American countries. Taking as a reference what has been mentioned, we will go on to answer the research questions.

RQ1. What are the best techniques and strategies for the implementation of telemedicine?

To answer the first question, it is necessary to review Table 4 where a classification of articles was made in order to answer that question. The first is to have a solid project plan as a fundamental basis for implementation, beyond complying with a political regime, for countries that are just beginning to incorporate telemedicine. The next section, and as a second option, is to have an alliance with the Ministry of Communications and Information Technology, which most Latin American countries have. As an implementation channel, it is necessary to analyze Figure 9, where the greatest evidence of having carried out a greater number of tests was found. The ATM (Asynchronous Transfer Mode) network technology by optical fiber is the most effective channel with 60% effectiveness for the implementation of telemedicine due to its high stability in connection, compared to the other implementation channels.

RQ2. Which are the medical specialties most benefited by telemedicine?

To answer the second question, it is necessary to review Figure 10, which shows the four medical specialties that have benefited most from telemedicine: dermatology, cardiology, endocrinology, and neurology. Dermatology is the most benefited specialty with a 28% of application currently due to its multiple uses, thanks to the sending of images of lesions or skin eruptions in the most prone areas where they can appear, even these diagnoses also serve to classify and detect urgent cases of diseases such as skin cancer. But when the case is very serious, it is clear that on-site care will be essential.

Conclusion

In this article, a systematic review of the literature on the impact of telemedicine in medical care has been presented, considering from 2015 to 2020. For this purpose, 50 articles were systematized, showing that the best strategy to implement telemedicine is to have a solid and integrated policy, and thus be able to implement successful health projects, among them telemedicine. Also, it is recommended to use the ATM network technology by optical fiber which evidences a high stability for an optimal connection. Finally, we clearly concluded which would be the medical specialties most benefited by telemedicine where dermatology is leading in implementation during the last years, therefore, it is recommended a greater application towards this specialty since currently there are many practices with favorable achievements. The results of this systematic review can be used for future research by researchers and professionals. In addition, significant methods derived from our study of systematic literature in the BD.

The Problem of Thin Capitalization for Financial Security of An Enterprise in Polish Financial System

Mariusz TOMCZYK
War Studies University, Warsaw, Poland, m.tomczyk@akademia,mil.pl

Tomasz KOSCIELECKI
Military University of Technology, Warsaw, Poland, t.koscielecki@wat.edu.pl

Abstract

The functioning of an enterprise, its essence and, above all, the purpose for which it was established (the profit of its owners) means that in each period of its functioning it is forced to search for sources of financing for its activities. The basic source of financing for any enterprise should be money generated by the enterprise itself. Business entities strive for the largest possible retention of capital in their hands apply tax optimization measures, including thin capitalization. The existing restrictions on thin capitalization introduce a mechanism to limit debt financing costs included in tax costs. This article characterizes the mechanism of insufficient capitalization and the changes that have taken place in it. The purpose of this article is an attempt to assess the importance of this mechanism for the financial security of the enterprise.

Keywords: thin capitalisation, financial security, income tax, enterprise.

Introduction

The functioning of an enterprise, its essence and, above all, the purpose for which it was established (the profit of its owners) means that in each period of its functioning it is forced to search for sources of financing for its activities. Due to constrained level of capital held and the need for financial resources (e.g. for development) this field is crucial for continuous existence of an enterprise. Ensuring the financial security of an enterprise is determined by stable financing of assets necessary to undertake short-term activities as well as strategic activities - implemented over a long period of time. The company's financial needs can be met from two sources - external and internal. Internal sources developed by the enterprise include, first and foremost, retained earnings, depreciation, issue of shares, increasing shares and decreasing the company's assets. On the other hand, external sources come from the financial resources of other entities like bank loans and borrowings, issue of debt securities, financial leasing, etc. (Kościelecki 2014). These are various forms of increasing the company's liabilities. This article characterizes the mechanism of insufficient (thin) capitalization and the changes that have occurred in its mechanism. The purpose of the article is an attempt to assess the importance of thin cap mechanism for the financial security of an enterprise.

Enterprise Financial Security

The goal of any business entity, regardless of its type, size or type of business, is to survive and to grow. Therefore, ensuring financial security is one of the basic conditions for the continuation and development of the company's operations on a competitive market. Without it, a given enterprise cannot survive or grow. Despite the widespread use of the concept of financial security of an enterprise, this issue is not clearly defined and raises a lot of controversy. There are many reasons for this situation, but undoubtedly one of the most important is the willingness of the entity to take risks. The term "security" is extremely often used and addressed to a wide variety of problems of human activity, natural phenomena, health, political and social situations and others. In general, security is most often associated with a non-threatening state for those values that are valuable. Enterprise security is such a field of its activity that guarantees its survival and the freedom to realize its interests (e.g. profit) (Koziej 2011). The financial security of an enterprise should be understood as a state that gives a sense of certainty of its existence and guarantees its permamence as well as development opportunities. It is defined as the company's ability to preserve the ability to settle current liabilities and high action efficiency (Franc-Dąbrowska 2006). Financial security means no threats to public finances, corporate finances, insurance, banking, or personal finances for households. It is important to emphasize that financial security is a major component of economic security.

Cite this Article as: Mariusz TOMCZYK and Tomasz KOSCIELECKI "The Problem of Thin Capitalization for Financial Security of An Enterprise in Polish Financial System" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

Considering financial security in the context of an enterprise, it is related to the entity's financial liquidity - the ability to pay its liabilities (Jachna 2016). Financial security is a process of continuous reduction and elimination of monetary risk in order to secure capital adequacy that will be tailored to the risk profile and preferences of a given entity (Płaczek 2014). One of the main determinants of financial security of an enterprise is its capital stock, or rather its amount, its adequacy to the entity's liabilities. The enterprise itself decides about the amount of liabilities of the business entity (loans, credits, etc.). The situation is different in case of the company's revenues and profits. The company's revenues will depend on the attractiveness of the product, the service it offers as well as the financial resources of its clients, their tastes, preferences, seasonality and, above all, the price of the product offered (market competitiveness). The company's profit is determined by the company's revenues and costs. The range of costs that can be taken into account in calculating the company's profit is defined by law. The wider the range of costs that can be taken into account when calculating the company's profit, the lower profit (gross) and lower income tax paid by the enterprise. That is why strict control of costs in the enterprise and the possibility of their qualification in tax sense is so important (both from the point of view of the state - tax recipient and enterprise - tax payer).

What is thin capitalization ?

In recent years, law provisions relating to thin capitalization have been amended many times, which changed some criteria, including entities providing financing, calculation of interest not included in tax costs or the degree of relation between the lender and the borrower.

In the legal status binding until the end of 2014, law restrictions in including tax costs related to financing granted by entities directly related to the borrower, having at least 25% stocks/shares if the value of debt exceeded three times the share capital of the recapitalized entity. Interest on such financing in the part exceeding the above limit (calculated at the time of their repayment) did not constitute tax costs for the borrower. However, in the years 2015 - 2017 the above provisions were amended, including the list of lenders who was expanded to include indirectly related entities. The method of setting limits on the cost of debt financing was changed from three times the borrower's share capital to the value of its borrower's equity, determined on the last day of the month preceding the month of interest payment.

Implementation into the Polish legal order of the regulations contained in the EU Council Directive 2016/1164 of 12 July 2016 and EU Council Directive 2017/952 of 29 May 2017 amending Directive 2016/1164 regarding discrepancies in the qualifications of hybrid structures regarding third countries (known as the ATAD Directive) establishing provisions aimed at counteracting tax avoidance practices that have a direct impact on the functioning of the internal market has caused changes in the mechanism of insufficient capitalization in Polish legislation.

Insufficient (thin) capitalization means a situation in which the owners equip the company with share capital (i.e. equity financing) to a minimal extent, while the company's operations are financed with return capital (loans, credits). In other words, insufficient capitalization is a kind of abuse by the shareholders (shareholders) of the repayable financing method, which consists in disrupting the ratio between the company's debt and its share capital (debt to equity ratio).

Current law restrictions on thin capitalization introduce a mechanism to limit debt financing costs included in tax costs. Pursuant to the Corporate Income Tax Act, enterprises that have their registered office or management board on the territory of the Republic of Poland are obliged to exclude from debt tax deductible costs the part in which the excess of debt financing costs exceeds 30% of the amount corresponding to the excess of the sum of revenues from all sources of income less interest income over the sum of tax deductible costs less the value of depreciation write-offs and debt financing costs included in the tax year and debt financing costs not included in the initial value of the fixed asset or intangible asset (CIT Act). This mechanism is based on two basic indicators - a limit of PLN 3 MM in excess of debt financing costs and a limit on excess of debt financing costs based on 30% EBITDA. Due to the content of the new provisions, it is justified to state that the thin capitalization mechanism in force so far, consisting in limiting the possibility of including part of interest paid to related entities (or owners) as tax deductible costs, has been replaced by a general exclusion from tax deductible costs debt financing costs, regardless of whether the costs indicated are related to transactions concluded by taxpayers with related entities or with unrelated entities. This means that taxpayers who do not receive any loans from related parties but finance themselves, e.g. through a bank, will also be required to exclude part of interest paid from tax deductible costs. The mechanism of the operation of insufficient (thin) capitalization is presented in the figure below.

Fig. 1 : Practical example of how thin capitalization works

Source: own study based on: (OECD, 2012)

The above figure shows that company B benefited from a loan from company A. It is important that under the current rules it does not matter whether the entities are related or not. In the first case the loan was 100 MM. The loan interest rate is 10%. Company B generates 20MM EBITDA. Debt financing costs are 10 MM. At the 19% income tax rate and assuming that there are no restrictions on deducting costs, the enterprise will pay an income tax of 1.9 MM in the annual tax settlement. With the existing restrictions on the calculation of debt financing costs and 20MM EBITDA, the annual income tax paid to the state budget will be 2.66 MM. The increase in the budget impact is caused by the limitation of eligibility of debt financing costs in the annual tax settlement. Debt financing costs include no more than 3 MM or (in the case of higher costs generated) up to 30% EBITDA. In this example, the cost of debt financing is 10 MM. The eligible costs in this example are 6 MM (30% EBITDA). The result of this limitation is the fact that the deduction of interest payment is 4 MM smaller in the annual settlement and thus the income is more taxable. Debt financing costs excluded from tax deductible costs in a given year, subject to meeting certain conditions, can be accounted for in tax costs in the next 5 tax years (CIT Act). It should be emphasized that the 30% EBITDA limitation works only if the costs of debt financing are higher than 3MM. For debt financing costs less than 3 MM, this amount is fully taken into account in calculating post-interest taxable profit. Example 2 in Fig. 1 shows this situation. In order to better present the importance of thin capitalization for the financial security of an enterprise, Figure 2 presents a model of the distribution of the company's tax liabilities.

Fig. 2: Distribution model of enterprise tax liabilities - graphic approach

Source: own study

The model assumes the following assumptions:

- the income tax rate is 19%;
- interest rate is 10%;
- there are no costs related to depreciation (EBITDA = EBIT); loan to EBITDA rate is 5.

Table 1 presents numerical values for the discussed model.

Table 1: Numerical values of the discussed tax model (Fig. 2)

	EBITDA	Loan	Paid tax (without limit)	Paid tax (limit applied)	Enterprise net income (without limit)	Enterprise net income (limit applied)	Additional contribution for enterprise/income for budget

Source: own study.

Under the adopted model assumptions, the operation of the insufficient capitalization (thin cap) mechanism causes, that above 30 MM of loan (deduction of interest payment is 3 MM=30MM*10%), the company's tax liabilities increase in comparison to the situation when no limit is set to include debt financing costs to the company's costs. The last column in Table 1 shows the amount of additional budget income/expenditure that the company must incur due to the mentioned limit. It is worth noting that the assumptions made in the model cause a linear increase of this amount.

Insufficient (thin) capitalization is therefore a source of more favorable interest treatment than dividends based on income tax. This phenomenon occurs when the company is financed by debt - through loans. The applicable regulations do not introduce a difference between debt financing in the form of a bank loan and loans granted by the shareholders of a given enterprise. In this case, loans granted by the shareholders are in fact hidden contributions to capital, and their purpose is to replace the company's share capital with loans/credits only to achieve measurable tax benefits (Fordońska, Partyka 2009) Financing a company's activity through credit is an attractive form of financing mainly due to tax benefits consisting in the possibility of including interest on the loan received as tax deductible costs, which reduces the tax base and thus the tax. Different tax effects occur in the case of final financing, which is the company's own funds, which may come from the shareholders' funds or from the company's own funds. **Thin capitalisation – is it still profitable?**

The previous part of the article showed that the introduced limit of including the costs of debt financing by an enterprise in its costs resulted in an additional cash inflow to the state budget and higher taxes for the enterprise. But how does the introduction of this limit affect the profits of the partners / shareholders of a capital company? Is crediting your business still profitable? In order to find an answer for this question and based on the model presented above, it was extended with further assumptions. The model considered below consists of the following assumptions:

- the income tax rate is 19%;
- the interest rate is 10%;
- there are no costs related to depreciation (EBITDA = EBIT);
- loan to EBITDA rate is 5;
- the company's profit is fully paid to its shareholders shareholders are the only loan providers.

Figure 3 presents a graphical model of the profit distribution of the company's shareholders.

Source: own study.

The presented model of shareholder profit distribution (maintaining the adopted model assumptions) shows that thin capitalization financing is still more advantageous compared to financing an enterprise wi-thout a loan. The chart clearly shows that the solution that brings the lowest income to shareholders is to finance the enterprise without borrowing from its shareholders. Using thin capitalization and taking into account the adopted income tax rate, the model shows a decrease in shareholders' income above 30MM of the value of loan. The table below shows exactly the differences in shareholders' profit depending on the adopted financial model of the enterprise.

Table 2: Numerical data presenting the distribution of shareholders' profits when using thin capitalisation and in the absence of it (Fig. 3).

			Calculations assuming that the shareholders provide a loan to the company					Calculations assuming that the company does not use the loan at all	
	EBITDA	Loan	Shareholders profit on the loan granted to the enterprise (after taxation)	Dividend paid to shareholders (after taxation, no thin cap limit)	Dividend paid to shareholders (after taxation, thin cap limit applied)	Total profit of shareholders (after taxation, no thin cap limit)	Total profit of shareholders (after taxation, thin cap limit applied)	Total profit of shareholders (after taxation)	Difference in shareholders profit (in favor of the credit model)
1	200 000	1 000 000	81 000	65 610	65 610	146 610	146 610	131 220	+15 390

Source: own study

The data presented in the table explain numerically the information contained in Fig. 3. The analysis of the model shows that despite the thin capitalization mechanism, this method of financing is still more profitable for shareholders. The data shows the measurable benefits of such a financial model. Assuming EBITDA = 200 000 and loan 1 000 000, the shareholders gain 15,390 in the tax settlement. With the extreme values in the model (EBITDA 11 400 000 and loan 57 000 000), the difference between the discussed methods of financing the enterprise is 526 338.

Conclusion

The current legal solutions mean that loan financing (while maintaining the established limitations) is still more favorable in the tax aspect due to the tax benefits consisting in the possibility of recognizing interest as tax deductible costs, which reduces the tax base and thus the tax. Different tax effects occur in the case of financial

costs higher than the established limits. In the presented model, up to EBITDA = 6 000 000 and loan = 30 000 000, the company's tax liabilities are of the same value (thin cap or without). Above these values, the company will pay more taxes on thin capitalization financing. Shareholders, on the other hand, feel the difference in the adopted model of financing the enterprise from the very beginning (in favor of loan financing). In the case of definitive financing, such as the company's own funds, which may come from the shareholders' funds or the company's own funds, the shareholder remuneration for the capital contributed to the company is a dividend. However, unlike interest, it cannot be accounted for as tax deductible costs. Moreover, the dividend is taxed twice - once as income at the company level, and the second time - as a dividend at the shareholder level (Tomczyk 2019). In the case of interest, double economic taxation does not occur. The payment of interest does not create a tax obligation as it is considered in the cost category. The presented benefits are the main reason for replacing equity capital with debt to a shareholder.

The mechanisms introduced to limit the inclusion of debt financing costs to enterprise costs are aimed at increasing the state budget revenues (as shown in the discussed model). It is worth to emphasize, that the current formula of the mechanism of insufficient capitalization (PLN 3 MM or 30% EBITDA) will have an impact on tax settlements mostly for relatively large enterprises. It seems that the change in regulations is dictated by trends that occur in this field internationally.

From the point of view of the state budget, the discussed issue is important because when the repayable financing is initiated (loans), the tax base is reduced by interest on loans (credits). Moreover, with regard to loans from foreign entities, this is disadvantageous to the Treasury if, according to the agreement on avoiding double taxation, interest is not taxed with withholding tax in Poland. In addition, the company's use of repayable financing, with a minimum shareholding, complicates the situation of the company's creditors, since it is much easier to return the loans granted by shareholders than the return of their capital contributions, and therefore in the first case there is a threat of depletion of the company's assets, from which the creditors they could potentially satisfy themselves. That is why most countries, including Poland, fight against thin capitalization using tax regulations. These laws take similiar forms in different countries.

Regardless of the adopted model, their application boils down to eliminating part of interest from tax deductible costs, which results in a higher tax base. The practice of creating tax law shows, that forms of tax optimization, especially those involving the use of loopholes in the law and inaccuracies, along with any amendment to tax laws are fought by the legislator.

A Fuzzy Set Analysis of Resources, Capabilities and University Spin-off Performance

Anna KWIOTKOWSKA

Silesian University of Technology, Gliwice, Poland
akwiotkowska@polsl.pl

Abstract

Prior literature does not sufficiently explain how different types of resources and capabilities contribute to perfomance of university spin-offs (USOs) nor does it clarify how these firms can combine different resources and capabilities to achieve superior performance outcomes. In addition, capturing performance outcomes of complex systems of interdependencies using commonly employed methods, such as regression models, is often difficult. Thus, this study employs a configurational approach, using fuzzy set Qualitative Comparative Analysis (fs/QCA), to analyze the resource and capability configurations of USOs that yield superior performance. The study finds no evidence of high-performing configurations without highly qualified human resources and shows that highly performing firms configure their resourecs and capabilities in three different ways. The results have implications for theory in the area of the initiation and growth of university spin-offs (USOs) as well as for configurational strategy research in general.

Keywords: Resources, Capabilities, University Spin-Off, Fuzzy Set Qualitative Comparative Analysis.

Introduction

Research related to university spin-offs (USOs) is attracting increasing attention, as they are now acknowledged as an important source of innovation that provides an impetus to regional and national competitiveness and economic growth (e.g. Shane 2004, Nicolaou, Birley 2003; Goldstein 2010; Newbert et al. 2008; Rothaermel et al. 2007; Stephan 2014). An USO can be defined as "a new company that is formed by a faculty, staff member, or doctoral student who left the university or research organization to found the company or start the company while still affiliated with the university, and/or a core technology (or idea) that is transferred from the parent organization" (Clarysse et al. 2011).

Many researchers claim that it is essential to recognize the heterogeneity and the context of USOs, because not all USOs are able, or required, to achieve high growth (Grimaldi et al., 2011), while high-growth USOs do play a particularly important role in university technology transfer and economic return. As a result, a couple of frameworks have been developed to assist research into USOs, while recognizing their heterogeneity, and empirical studies have identified a range of factors facilitating or hindering the initiation and growth of USOs (e.g. Colombo, Piva 2012; Iacobucci, Micozzi 2014; Knockaert et al. 2011, Scholten et al. 2015; Visintin, Pittino 2014).

Resource heterogeneity has been emphasized as one of the major themes besides institutional diversity and business model differences, however, a limited number of attempts have been focused on the configurations of resources and capabilities and their performance implications in the area of USOs. What is more, one of the major challenges that new ventures face with is to identify and acquire the appropriate resource base. The main focus of the literature is, however, on the effects that are contributed to the venture's success by individual resources. This approach enables the identification of the basic, most significant resources necessary for a new venture to develop; however, it does not explain the iterations and relationships existing between resources in the context of this so complex business phenomenon. Moreover, in line with the approach of the resource-based theory, resource bundles and competitive advantage underlie resource-based configurations (Heirman, Clarysse, 2004). These configurations are built by

managers using the capabilities of the organization. It is also essential to determine how the resources interact and how resources and capabilities contribute to performance. In this context, the overall view is provided by the configurational approach that enables the full understanding of the connections between the resources and capabilities and their performance implications.

A configurational approach comes, with several challenges. Theoretically, researchers have to take a novel approach because different factors may lead tomultiple configurations with comparable outcomes. In configurational analysis, therefore, the focus shifts from the net effect of a single characteristic on performance to the analysis of multiple configurations associated with high performance. Empirically, configurational arguments also face the methodological challenges of modelingmultiple, complex relationships between the elements of a configuration (Fiss 2007, 2011). To overcome the methodological challenges of testing the configurations of resources and capabilities, the current research uses fuzzy set qualitative comparative analysis (fs/QCA), a set-theoretic configurational approach with the ability to handle high degrees of complexity in how different causal conditions combine to bring about an outcome (Ragin, 2000, 2008). This research attempts to develop an analytical framework based on fs/QCA in order to answer the following research questions: How are bundles of resources and capabilities configured in the area of the initiation and growth of USOs?; and How are these configurations associated with high performance outcomes? This research attempts to construct a framework for analyzing USOs in general by gaining a better understanding of the initiation and growth process of USOs in emerging economies. On the other hand, this paper seeks to improve the understanding of the resource-performance link by demonstrating how resources and capabilities contribute to USOs performance and what different resource and capability configurations lead to high performance outcomes.

The remainder of this paper is structured as follows. First, a brief literature review of research related to the configurational approach and resource-capability configurations in USOs is provided and the conceptual framework is introduced. Next, method and data is described and the results of empirical analyses is presented. The concluding section discusses the implications of findings for the development of USOs and also for theory and practice.

Theoretical background

Many researchers have claimed that it is essential to recognize the heterogeneity and context of USOs (e.g. Colombo, Piva 2012; Grandi, Grimaldi 2003; Grimaldi et al. 2011; Knockaert et al. 2011, Rasmussen et al. 2011, Scholten et al. 2015; Wright et al. 2008; Visintin, Pittino 2014) before addressing their growth potential, rather than to negate the value of USOs in haste. The heterogeneity of USOs has been studied from different theoretical perspectives. The first stream of research uses the resources-based approach. Further, there exists research that considers the diversity of resources within USOs, including the nature of the technology, the source of the resources, the company's financial resources, their social networks, their initial resource and other resources. Another area of research reported in the literature distinguishes the types of USOs based on their business model. Studies conducted in this area encompass the characterization of activities associated with the growth of USOs, distinguishing the sectors in which those firms are located and indicating to the key indicators that make them different from other start-ups. The third perspective of conducted studies is related to the links of USOs with their parent organization and the research conducted within the institutional environment, from which those firms originate. Thus, resource heterogeneity has been emphasized as one of the major themes besides institutional diversity and business model differences; however, limited attempts have been focused on the bundles of resources and capabilities, which lead to high performance, and much less, on determining whether alternative resource and capability confirgurations exist, which will equally lead to high performance (the equifinality concept), while enabling USOs to grow and survive in the market.

The configurational approach represents one of the main directions of research on the subject of strategic organization and management found in the literature (Fiss, 2007). This approach is of particular interest due to the multidimensional nature of an organization, where the competitive advantage relies not on a single attribute, but instead on mutually complementary, complex and diverse characteristic features. As Fiss (2007: 1188) argues, the configurational approach emphasizes that organizations are best understood as the associations of interrelated structures and practices rather than modular or loosely connected wholes, whose components could be understood separately. Importantly, aside from offering a more holistic perspective to the understanding of organizational activities, configurational approaches facilitate insights into the equifinality of different configurations (Fiss, 2007). What is more, configurations are an important means of capturing the complexity of an organization and understanding the relationship between the

organizations and their performance outcomes. It can therefore be assumed that if resources and capabilities are really related, one should be able to distinguish between different types of resource and capability configurations.

This research is embedded in the resource- based view of the firm literature (Barney, 1991; Teece et al., 1997), which considers the resources and capabilities of a firm as a predictor of competitive advantage and growth. The goal is to bring out the differences in the resources and capabilities of USOs and identify the common patterns of relationships between resources and capabilities and their performance implications. Although extant research has revealed little about the configurations of resources and capabilities, there is some body of work that has investigated the role of resources and capabilities in the creation and development of USOs, and that can serve as a guideline for identifying the relevant resources and capabilities in this area. While one might be tempted to include a long list of resources and capabilities in a conceptual model, prior studies have warned that such a procedure can result in spurious variables that impede the detection of configurational cluster structures in empirical data. Therefore, the number of resources and capabilities considered has been limited by focusing on a set of core constructs that are literature-based to ensure their theoretical and empirical relevance.

The literature on entrepreneurship shows that start-up business ventures differ significantly mainly in financial resources, technological resources and human capital (e.g. Delmar et al., 2013; Druilhe and Garnsey, 2004; Heirman, Clarysse 2004; Lundqvist, 2014; Miozzo, DiVito, 2016; Wennberg et al., 2011; Wright et al., 2012, Vohora et al., 2004). It should be emphasized that, in turn, organizational cannot be easily acquired by new ventures as they are built over time. Thus, at the beginning, that is when a new venture starts operation, organizational resources are not developed. Hence, organizational resources were not included in the research concept.

From a capabilities perspective, a few studies have focused on the creation and survival of USOs, e.g. (i) the knowledge and complementary capabilities of USOs (Colombo, Piva, 2012); (ii) the capabilities of the entrepreneurial team (Clarysse, Moray, 2004); (iii) the capability to obtain financial resources (Wright et al., 2012); and (vi) the innovation capability (Zhou, Minshall, Hampden-Turner, 2010) however, research that investigates capabilities together with resources needed for achieving high performance outcomes in a configurational approach remains sparse.

Importantly, one of the methods of using the configurational logic to entrepreneurial organizations, which undoubtedly USOs are, is to consider the cognitive patterns of entrepreneurial thinking, and especially entrepreneurial capabilities. The identification of leading entrepreneurial capabilities will cast more light on the relationships between entrepreneurial thinking and outcomes, such as the performance of organizations. For example, some configurations of organizations may have high intensity of innovativeness and low intensity of the other components, while some patterns can be better adjusted to given situations than others. Entrepreneurial capability is considered to be a latent multidimensional construct (Covin, Slevin, 1989). According to Covin and Slevin (1989), innovativeness, proactiveness, and risk-taking are the central aspects of the entrepreneurial behaviour of entrepreneurial firm.

A growing body of literature has considered the importance of networks and networking capability for the initiation and growth of new entrepreneurial ventures (Zheng et al, 2020). Start-up can enhance its early performance by establishing broad networks to overcome the limitations of newness at reduced cost. Moreover, network relations act as a bridge to gain access to information and resources that supplement the entrepreneurs' or nascent firms' own assets (Delmar, Shane, 2004). There is general support for the notion that entrepreneurs with a more developed network, in terms of the quality and number of ties, are more likely to succeed and reach high performance than those having a less developed network.

Therefore, in terms of capabilities, the research approach in this paper has been based on the understanding of innovation capabilities and entrepreneurial capabilities. So, in accordance with the previous assumptions, by simplifying the construct to core constructs and taking into consideration the determinants of the establishment and growth of USOs, the following capabilities have been included in the framework: networking capability and innovative and risk-taking capability. The theoretical framework is shown in Figure 1. It is worth reiterating that the present study seeks to advance the knowledge of the resource-performance link by exploring bundles or configurations of resources and capabilities. To investigate these issues, the fs/QCA was used as discussed in the next section.

Method and data

The type of research selected by the author was the multiple case study, in which several cases were studied simultaneously within a single research undertaking. A consequence of the selected research method was the non-random, intentional choice of a sample from Polish USOs. The selection of enterprises was guided by the following criteria: the selected enterprises are relatively new, developing business ventures relying on the transfer of knowledge (as seen from the aspect of the transfer of intellectual assets, and not only technologies), set up by young persons being final-project students, doctoral students, or academics. The research was conducted in the form of interviews with the founders or management representatives of 53 USOs, in the period from April to November 2019.

Information collected from the surveys and from other sources (e.g. the internal documentation of the enterprises, archival data, websites) was used for carrying out an analytical procedure using fuzzy set Qualitative Comparative Analysis (fs/QCA) - set-theoretic analysis technique. The aim of fs/QCA is not to prove the existence of causal relationships but rather to reveal patterns that support the existence of causal relationships (Schneider, Wagemann, 2010). Set-theoretic analysis examines causal patterns, focusing on relationships among subsets. This study uses fs/QCA to identify configurations of resources and capabilities that contribute towards high performance in 53 Polish USOs. In theoretical and empirical terms, it is a novel context in which to use fs/QCA. What is more, the USOs, as relatively young firms, are typically less complex than more established firms, so they provide a comparatively clean setting for an empirical exploration of the effect of resources and capabilities. Thus, by using fs/QCA in this context, it is possible to illustrate the value of this nascent approach while addressing an important gap in the current scientific literature on the management of entrepreneurial organizations.

To explore the ways in which resources and capabilities might influence the performance outcomes of USOs, fs/QCA treats each possible configuration of key variables as a single case and identifies the necessary and sufficient causal

conditions associated with each configuration. Through comparison, these cases are reduced to the minimum combinations of causal factors (e.g. resources, capabilities) necessary for an outcome to occur (e.g. performance outcome). The analysis also uses consistency and coverage as two key parameters for assessing the fitting of the fs/QCA results to the underlying data.

Consistent with prior research, the perceived measurement of firm performance was used, where the respondents rate their performance in relation to their competitors. According to Chandler and Hanks (1994), asking firms to evaluate their performance by comparing themselves with their competitors leads to a higher level of reliability and validity. To illustrate the performance outcomes a tool invented by Antoncic and Hisrich (2001), were used (alpha = .95). The items used to measure financial, technological and human resources came from the study by Heirman and Clarysse (2004). The operationalisation of networking capability is based on a refined version of Walter, Auer, and Ritter (2006) research (alpha = .87). From these studies, three items were selected that measure each of the four dimensions (coordination activities, relationship skills, partner knowledge and internal communication). Innovative and risk-seeking capability refers to a firm's overall innovativeness and proactiveness. Innovative capability refers to a firm's ability to espouse new and creative ideas, products, or processes designed to service markets (Lumpkin, Dess 1996). Risk-seeking capability refers to firms' ability to undertake significant and risky resource commitments in markets. The measures of innovativeness and risk taking (alpha = .83) were taken from the work of Covin and Slevin's (1989). The study uses 10 interviews in various companies to evaluate the questionnaire on interpretability and ease to complete. Several items had slightmodifications based on managers' answers.

The condition and outcome variables differed in their underlying forms and were recoded for inclusion in the analysis on a continuous scale from 0 to 1 (Ragin, 2008). Subsequently, a direct coding method was utilized to code individual case data points (as explained in Ragin, 2008). The direct method focuses on the three qualitative anchors that structure the degree of membership to the focus set. These are: (1) the threshold for full non-membership; (2) the threshold for full membership and; (3) the cross-over point, where there is some ambiguity about membership.

The next analytic step is the consideration of causal configurations of conditions and the outcome, here elucidated through truth tables. The truth table represents logically possible combinations of included conditions and is the key tool of set-theoretic analysis (Ragin 2008). The important point is that the rows in each truth table are not specifically representing individual cases, but the logical configurations for which they were strongly associated at each one case (with five conditions considered there are 25 = 32 logical configurations).

Next, the causal conditions most strongly linked with the perfrmance outcome was considered. This fundamentally comes down to seeing what combinations of causes discern those configurations. Prior to this, consideration has to be given to those configurations which are not included in the respective truth table. These are configurations that are theoretically plausible, but not empirically present. The inclusion of the remainders in the analysis, by considering their association with the absence of the outcome, leads to what is called the 'complex' solution. An alternative is to exclude the remainders from the analysis. This is termed the parsimonious solution. Between these there is a solution 'guided by theory', which attempts to assign the outcome to logical remainders, termed the intermediate solution (see Ragin, 2008). Importantly, the different treatments of these logical remainders lead to different solution formulas. However, all formulas are logically true because they do not contradict the available empirical information contained in the truth table. The fs/QCA 2.5 software was used in the analysis, which provided results consisting of a complex solution, a parsimonious solution and an intermediate solution.

Results

In this research the parsimonious and intermediate solutions are presented and analyzed. The results from the parsimonious and intermediate solutions can be summarized using a configuration chart – Table 1. Utilizing the notation system from Ragin and Fiss (2008), each column in Table 1 represents a configuration of conditions linked to the respective outcomes. Full circles (●) indicate the presence of a condition while blank spaces indicate "don't care". Each panel represents the alternative causal combinations or recipes for the outcome (Ragin, 2008). These are consecutively numbered S1a, S1b, S2.

Table 1: Configurations for high USOs performance

Configuration	Solution		
	S1a	**S1b**	**S2**
Conditions			
Financial resources	●	●	
Technological resources			●
Human resources	●	●	●
Networking capability	•		•
Innovative and risk-seeking capability		•	•
Consistency	0.91	0.92	0.98
Raw Coverage	0.53	0.64	0.61
Unique Coverage	0.01	0.12	0.06
Solution Consistency	0.92		
Solution Coverage	0.75		
Note: ● = core causal condition present; • = peripheral causal condition present.			

Source: own study

In brief, consistency measures the degree to which cases sharing a given condition agree in displaying an outcome. Raw coverage measures the overall coverage of a combination that may overlap with other combinations. Unique coverage refers to coverage uniquely due to a combination. Solution consistency measures the degree to which membership in the solution (the set of solution terms) is a subset of membership in the outcome. Lastly, solution coverage refers to the combined coverage of all combinations leading to the outcome (see also Ragin, 2008).

Table 1 indicates that there are three core conditions associated with high performance, namely the presence of human resources in all three solutions, financial resources in solutions S1a and S1b and technological resources in solution S2. Regarding overall coverage, the solution accounts for 75% of membership in the outcome and, thus, presents acceptable fit. Further, all three configurations show high consistency values from 0.91 to 0.98,with the overall solution consistency at 0.92. The overall solution for high performance implies first-order (or across-type) equifinality of solutions. The neutral permutations within solution 1 (1a and 1b) imply second-order (or within-type) equifinality.

As for the peripheral conditions related to high performane, the analysis indicates that in solution S1a the core conditions are complemented by networking capability. So, this group includes USOs in which the scientific mastery combines with the managerial talent, being grounded not only on considerable, broad experience (in the market, in management, and in a given scientific discipline), but also on numerous contacts and network links with the shareholders, industrial partners or support units. These firms have obtained considerable capital support, coming mainly from investors, less often from venture funds. For solution S1b, the core conditions are complemented by innovative and risk-seeking capability. This group includes enterprises, which are additionally characterized by high proactiveness and innovativeness. So, the primary motivation for establishing a firm of this group was the self-employment, self-direction in recognizing, taking and using opportunities, and the willingness to act independently. Moreover, emphasis is laid in these firms on research and development, innovations, and the employees are encouraged

to think and act in an original and novel way. Solution S2 indicates that technological resources and human resources as a core conditions with networking capability and innovative and risk-seeking capability as a peripheral conditions leads to high perfomance of USOs. These firms have innovative technologies, manufacture technologically advanced products, chiefly on their own, and have substantial market share, not only in the domestic but also the world's market. Interestingly they have high networking and innovative and risk-seeking capabilities. This type of USOs have the ability to coordinate relationships, build knowledge about partners, as well as relational skills. They are operating in dynamic environments where proactive distance search efforts are often necessary to drive innovation and performance. This firms strongly emphasize the need to drive innovation

Discussion and Conclusions

This study, through the use of fs/QCA, sought to improve our understanding of the resource-performance link by investigating the following main issues. First, it demonstrates how bundles of resources and capabilities are configured in the area of the initiation and growth of USOs. Second, it enables one to examine how these configurations are associated with high performance outcome. This study confirms that different combinations of resources and capabilities can lead to the same outcomes - high USOs performance. The analysis has identified three alternative causal combinations of resource and capabilities. This finding provides many interesting insights for entrepreneurship research, especially with regard to the initiation and growth of USOs. Importantly, the results suggest that the presence of innovative and risk-seeking capability or networking capability with human resources are strongly associated with high performance in the case of surveyed population of Polish USOs. It's also interesting to discover configurations of innovative and risk-seeking capability and networking capability with human and technological resources.

Despite the strengths of the results presented here, the findings do raise many questions about the nature of resource and capability configurations and their impact on the performance of USOs, which are worth further research. One of the many advantages of fuzzy analysis over crisp set-theoretic analyses is that it can accommodate gradations in the focal outcome variable. Subsequent work could therefore follow Greckhamer's et al. (2018) example and go beyond the binary outcomes of high or low performance to investigate multiple gradations of performance from very low, low, quite low, neither low nor high, right through to very high. This would vividly illustrate the singularity of individual causal configurations and allow the full range of causal asymmetry across possible configurations to be explored in the greatest detail.

At the same time, it might happen that attributes other than those considered in this analysis are equally able to distinguish between high performance outcome in the case of USOs. Moreover, another measure may be used to illustrate the performance results. Variables such as social capital, customer orientation and cognitive diversity are all identified as critical intangible resources in the strategic management literature. Set-theoretic analyses that brought together the measures of these variables with those that are identified as core conditions in this analysis, would cast valuable new light on the nature of USOs. For now, it is safe to say that fs/QCA offers a powerful means to theorize and test for the presence of complex attribute configurations in entrepreneurial organizations.

Organizational Pride, Work - Life Balance, Leadership Style, Rewards and Job Satisfaction in SMES. QCA

Magdalena GEBCZYNSKA

Silesian University of Technology, Gliwice, Poland, Magdalena.Gebczynsk@polsl.pl

Abstract

Lack of attention to job satisfaction as basic human needs leads to some organizational abnormalities and insufficient reactions at workplace. The purpose of this article is to examine how different factors, such as: organizational pride, work - life balance, leadership style and rewards simultaneously affect the employee job satisfaction in SMEs. The fuzzy-set Qualitative Comparative Analysis was used. The paper is structured as follows. First, the four factors connected to employee job satisfaction were analysed. Then the sample used was described together with the measures used for each variable involved. Finally, the main results obtained were shown and discussed, and conclusions were drawn regarding future research directions.

Keywords: job satisfaction, SME, QCA

Introduction

The small and medium enterprises (SMEs) are significantly important to the Polish economy, and like in other countries, SMEs are driving force of growth and development. Nowadays, attracting and retaining of reliable and competent employees is the big challenge to the organization in the competitive business labour market. An unsatisfied employee is the first enemy of the organization. A satisfied employee will be an asset to the organization. When employees are satisfied with the work they do, they become happy and produce better results than when they are unhappy, that's why motivating and retaining qualified employees is very important in ensuring the success of organizations (Sohail and Jang, 2017). One of the main items that improves human resource is job satisfaction and should be support by managers of organizations (Wegge et al., 2007).

Job satisfaction is the Holy Grail of organizational psychology (Mitchell et al., 2017). The presence of job satisfaction among staff assumed as positive factor that improve and increase level of organization outcome (Tazekand, Nafar and Keramati, 2013). Job satisfaction affects a person's general wellbeing for the reason that people spend a good part of the day at work. Consequently, if a person is dissatisfied with his work, this could lead to dissatisfaction in other areas of his life.

One of the most widely used definitions in organizational research is that of Locke (1976), who defined job satisfaction as a pleasurable or positive emotional state resulting from the appraisal of one's job or job experiences. Employee job satisfaction according to Gu, Zhen, Song, and Xu (2019) is a measure of people's contentedness with their job and an assessment of their work experience. The presence of job satisfaction can increase personal efforts, communications, staff abilities, the amount of personnel tendency toward their job and totally helps to growth of an organization (Aziri, 2011). Belias and Koustelios (2014) elaborate job satisfaction as the employees' perceptions of their working environment, relations among colleagues, earnings and promotion opportunities. Satisfied employees are adherence towards their work which lead to improve their performance, and the success of an organisation is highly depends on the performance of the employees. The purpose of this article is to identify and indicate the constellation of factors simultaneously affecting employee job satisfaction in small and medium enterprises. With this aim, the main theoretical and empirical studies on this subject have been revised.

Based on literature review and on previous research conducted by author, to analyse in this research four factors were chosen: organizational pride, work - life balance, leadership style and rewards. Previous research, resulted in partial view on job satisfaction and shows that numerous, single factors or phenomena have effects on employee job satisfaction. These research are devoid of a global view to indicate how different factors simultaneously affect job satisfaction. Using fuzzy- set qualitative comparative analysis (fs/QCA), this study examines the complex ways to achieve employee job satisfaction. A set-theoretic configurational approach, with the ability to handle high degrees of complexity in how different causal conditions combine to bring about an outcome. QCA explicitly allows for

equifinality of different combinations of causal conditions. Equifinality means that different configurations of causal conditions (factors) can lead to the same outcome - employee job satisfaction.

Theoretical Framework

Based on a broad and critical analysis of the literature and on previous research conducted by author, chosen factors influencing employee job satisfaction will be characterized below. Organizational pride is essentially a psychological structure examined in psychology studies with a particular focus on the relationship of employees with their organizations (Haslam, 2004). In general, pride is a positive emotion that signals success and nurtures an individual's self-perception, a central human need (Kraemer et al., 2017). Organizational pride consists of feelings of admiration, importance, and value based on evaluations of status made by staff (Todd, and Kent, 2009). Pride is a positive, self-conscious emotion that is based on success (Tracy et al. 2009).

Organizational pride has been the subject of research and interest of both management practitioners and scientists as a key factor of enterprise success and due to its impact on positive employee behaviour (Katzenbach, 2003). Research on organizational pride suggests a significant and positive relationship between pride and job satisfaction (Gunter and Furnham, 1996). Organizational pride is referred to as an encouraging constructive work environment that needs high social recognition with the organization (Kraemer and Gouthier, 2014) and it is an important factor for business success (Gouthier and Rhein, 2011). Appleberg (2005) states that organizational pride influences the decision to stay in a company and stimulates employee commitment.

Research on organizational pride has shown the impact of pride on job satisfaction (Gunter and Furnham 1996; Arnett et al., 2002). Employees who are identified with their work and who are proud to work in a enterprise are also satisfied in their jobs (Van Dick et al., 2004). Furthermore, organizational pride is considered as an antecedent of job satisfaction when it is referred to employee's emotional attachment to, identification with and involvement in the organization (Lok and Crawford, 2001).

Organizational pride involves high appreciation for and a strong emotional attachment to the organization. Kraemer and Gouthier (2014) divided organizational pride into two types, the first is emotional pride and the second is attitudinal pride. Emotional pride is pride which is strong but discrete contrast to emotional pride, organizational pride in attitudes is collective, resulting from the staff desiring to belong to the company (Fisher and Ashkanasy, 2000).

Work-life balance is a term refers to maintaining an optimum balance amidst work roles, life roles and personal responsibilities and therefore becomes a crucial concern that demands attention (Haar et al., 2014).

There are different views on how work-life balance should be defined, measured and researched (Grzywacz and Carlson, 2007). A healthy work-life balance assumes great significance for employees particularly in the current context in which both, the family and the workplace have posed several challenges and problems. Work-life balance is multi-disciplined consisting of labour economics, human development, organizational behaviour, psychology, sociology, women studies, demography, management and industrial relations (Drago and Kashian, 2003). Kalliath and Brough (2008) proposed a definition of work–life balance drawn from the occupational stress theoretical framework, i.e. work–life balance as the individual's perception that work and non-work activities are compatible and promote growth in accordance with an individual's current life priorities (Kalliath and Brough (2008). Swami (2007) defined work-life balance as a practice that is concerned with providing scope for employees to balance their work with the responsibilities and interests they have outside work.

A work-life balance is all about people having a control over the work when, where and how they do (Kamau et al., 2013). An effective work-life balance assists a person in achieving both personal and professional goals (Oludayo et al., 2015). Schermerhorn (2013) revealed that work-life balance is the ability of a person to balance the demands of work with their personal and family needs. Based on earlier research and findings (e.g. Ojo et al., 2014; Oludayo, et al., 2015), there is relationship between work-life balance and different variables. The last findings (Pathak, Dubey, and Singh, 2019) directly indicate that work life balance has a deep impact on individuals/employee job satisfaction in industries. The higher the level of balance in the work life of an individual employee the higher will be his commitment to his work and more will be the satisfaction in his job. Kasbuntoro et al.(2020) state similarly, namely work-life balance have a significant influence on job satisfaction.

Research of the management and organizational behaviour fields shows that the leadership style of managers influences employees' job satisfaction (Judge et al., 2001). Leadership has deep relevance and influence on the human resources of a firm in terms of attracting people to achieve the goals of organizations (Skansi, 2000) and it is critical for organizational success (Bryant, 2003). Employee's satisfaction is linked to a lot of external factors such as leadership styles which effect on staff's feeling and change their attitudes about job (Bahadori, 2012; Khera and

Gulati, 2012). Leadership is the ability of a manager to influence, motivate, and enable employees to contribute to organizational success (Having, 2011). Leadership as a management function is mostly related to human resources and social interaction. It is the process of influencing a group of people towards achieving organizational goals (Skansi, 2000). Leadership styles vary from situation to situation (Lok and Crawford, 2004). Most leaders adapt their leadership style in accordance with the demand and working environment of an organization (Zahari and Shurbagi, 2012). There is no universal leadership style, and different leadership styles are needed for different situations. An effective leader must know when to exhibit a particular approach. Rowold et al. (2014) propose that the leadership style of an employee's supervisor positively affects the employee's organizational commitment and job satisfaction. Leadership behaviour of managers plays a critical role in employees 'job satisfaction and commitment (Wu et.al.,2006). The leadership style always directly or indirectly affects the job satisfaction of the employees in their organization. Research indicate that transactional leadership style and transformational leadership style have a positive relationship with employee's job satisfaction in small and medium enterprises (Sakiru et. al, 2013).

Rewards aim to motivate employees to work better so they can improve their performance. Awarding is one of the ways that companies can do to improve the performance of their employees. Edwards et al. (2006) explained that rewards were received as an exchange of services between employee and employer. The reward can affect job satisfaction and employee performance (Riasat et al., 2016). Employee reward is about how people are rewarded in accordance with their value to an organisation and includes both monetary and non-monetary rewards. Gerald and Dorothee (2004) indicate that job rewards are strong determinant of job satisfaction and also rewards are significantly related to professionalism and job satisfaction and that employees' job satisfaction is affected by both financial and non-financial rewards.

Delineation between intrinsic and extrinsic rewards was recognised for the first time during 1950s by Herzberg ,who suggested two types of rewards:(a) intrinsic or job content factors (related to the job itself) such as achievement, recognition, and advancement (so-called motivators), and (b) extrinsic or job context factors (factors around the job, settled within the working environment) such as pay, job security, and working conditions (so-called hygiene factors). Rehman et al. (2010) found that extrinsic rewards are strong relationship with job satisfaction as compared to intrinsic rewards. Researchers suggested that intrinsic factors has a significant impact on job satisfaction of employees. Putra et al. (2018) mentioned that an intrinsic reward is a form of self-satisfaction what has an influence on job satisfaction.

Methodology of Research

This study identified which constellations of chosen factors are conducive to the employee job satisfaction in small and medium enterprises. The chosen factors consisted of: organizational pride, work - life balance, leadership style and rewards. This study used the survey technique to better understand the determinants of job satisfaction in Polish SMEs. Data were collected from SMEs in Poland during the first quarter 2019 and the fieldwork contains information from 97 surveys. After the exclusion of incomplete questionnaires, data for the analysis comprises 81 valid surveys, representing a response rate of 83,50%. All questions were presented in the form of 5- point Likert scales, where respondents indicate their level of agreement/disagreement All item loadings are higher than 0.7. An extensive review of the relevant literature supports the validity of the scales (Table 1). From a psychometric perspective, one single-item overall measure captures job satisfaction was used. The use of single-item measures to operationalize this construct (Cronbach Alpha = 0.929) compares favourably with the use of multiple-item measures (Dolbier et al., 2005). Research model is presented in a Figure 1 and it is verified in the process of scientific research.

Table 1: Scales measurement

Factors	Adapted from	Cronbach Alpha
Organizational pride	Construct was measured by 3-items from Gouthier and Rhein (2011)	0.89
Work-life balance	Construct was measured by 4 items from Brough et al. (2014)	0.93
Leadership style	Construct was measured by 20-item Leadership Style Questionnaire, developed by Northouse (1997)	0.92
Rewards	Rewards practices were measured using a 6-item proposed by Tessema and Soeters (2006)	0.82

Source: own study.

To analyse the data a set-theoretic approach was chosen, specifically fuzzy set Qualitative Comparative Analysis (fs/QCA). The fs/QCA 2.5 software developed by Ragin and Fiss (2008) used to analyse the data. According to Ragin and Fiss (2008), fs/QCA is suitable for samples of 10–50 cases. Unlike the reliance of symmetric (correlation-based) methods on matrix algebra, fuzzy-set QCA uses Boolean algebra to specify and test recipes (Ragin and Fiss, 2008; Woodside, 2015). The process of QCA starts with defining the property space which comprises all configurations of conditions leading to an outcome. Given that "the property space delimits potential explanations of the outcome, the (conditions) should be chosen carefully and anchored in extant theoretical knowledge" (Ordanini, et al., 2014). In fuzzy-set QCA, both the causal conditions (the four chosen factors) and the outcome (job satisfaction) are represented using fuzzy membership scores (Ragin and Fiss, 2008), which requires calibrating all variable scales to range from 0.00 for full non-membership to 1.00 for full membership. To perform fuzzy-set calibration, criteria are necessary for three breakpoints, set at 0.05 for the full non-membership threshold; 0.50 for the crossover point; and 0.95 for the full membership threshold (Ragin and Fiss, 2008).While the continuum between these two extremes reflects varying degrees of membership, the crossover point represents cases that are neither in nor out of the set (Schneider et al., 2010). Table 2 shows the calibration process and indicates the transformation of both the outcome and the antecedent conditions into fuzzy terms.

Table 2: distribution of each variable and its corresponding set

Variable	Full non-membership (0.05)	Crossover point (0.5)	Full membership (0.95)
Organizational pride	0.180	1.610	3.814
Work-life balance	0.237	2476	5.220
Leadership style	0.253	3.012	5.632
Rewards	0.336	3.029	5.742
Job satisfaction	0.339	2.591	4.612

Source: own study

The analysis of sufficient conditions involves three steps (Ragin and Fiss, 2008): construction, preparation, and analysis of the truth table. Reduction of the truth table shows several useful statistics. Overall solution consistency indicates the degree to which the sub-set relationship holds for sufficiency. The overall solution coverage refers to the joint importance of all causal paths. Unique coverage of causal conditions is similar to unique R-square calculations in regression analysis in that it illustrates the relative weight of each path by measuring the degree of

empirical relevance of a certain cause or causal combination to explain the outcome. Reduction of the truth table is carried out by the Quine-McCluskey algorithm which provides a logical reduction of statements (Ragin and Fiss, 2008). A necessity test was executed to examine whether there is a single condition in all configurations to job satisfaction. A condition is necessary when its consistency is above 0.9 (Skaaning, 2011), which indicates the degree to which a condition is present in all cases with the same outcome. In this study no necessary conditions were found.

Results

Based on the conceptual model presented above, a questionnaire was developed and series of surveys was carried out to collect data on job satisfaction in SMEs. The research model links the causal conditions (organizational pride, work - life balance, leadership style and rewards) to the outcome (job satisfaction). Two constellation were found to lead to high job satisfaction. The first constellation (C1) combines work-life balance, leadership styles and rewards. The second constellation combines the presence of organizational pride and leadership styles. The results of empirical research was presented in Table 3.

Table 3: constellation of factors lead to high job satisfaction

Factors	Constellations	
	C1	C2
Organizational pride		●
Work-life balance	●	
Leadership style	⬤	⬤
Rewards	●	
Consistency	0,91	0,89
Raw coverage	0,40	0,31
Unique coverage	0,04	0,03
Solution consistency	0,87	
Solution coverage	0,59	

Source: own study

Raw coverage refers to the total percentage of cases with the associated outcome that is represented by a solution term. Raw coverage refers to the total percentage of cases with the associated outcome that is represented by a solution term. 40 % of the cases that represented the job satisfaction in SMEs are represented by constellation C1, 31% by C2. Unique coverage refers to the percentage of cases that is only represented by the regarding constellation and not simultaneously by another constellation. Consistency refers to the percentage of cases of a configuration that result in the associated outcome. The overall solution consistency of the constellations of factors of complex causal recipes that can lead to the job satisfaction in Polish SMEs is 87%. The overall coverage of 59 % indicates that the three solution terms jointly cover 59% of the cases. Utilizing the notation system from Ragin and Fiss (2008), each column in the Table 3 (C1, C2) represents a constellation of conditions linked to the respective outcome. Full circles (●) indicate the presence of a condition, while blank spaces indicate "don't care". Further, core and complementary conditions are distinguished by the symbols' size: larger circles indicate core conditions that are part of parsimonious solutions. Smaller circles indicate complementary conditions that only occur in intermediate solutions. Each panel represents the alternative causal combinations or paths for the outcome (Ragin and Fiss, 2008).

Discussion and Conclusion

The first constellation of the factors (C1) combines work-life balance, leadership style and rewards. Table 3 indicates that there are one core condition associated with job satisfaction, namely leadership style, which is complemented by peripheral conditions associated with job satisfaction – work-life balance and rewards. This constellation indicate that the ability of a manager to influence, motivate, and enable employees to contribute to organizational success, and providing scope for employees to balance their work with the responsibilities and interests they have outside work, and with job content factors such as achievement, recognition, and advancement and with job context factors such as pay, job security, and working conditions lead to job satisfaction.

The second constellation of factors (C2) combines leadership style and organizational pride. Interestingly, as in the previous solution, the results show that there is one core condition associated with job satisfaction, namely leadership style. In terms of peripheral conditions associated with job satisfaction, the QCA suggest, that the core condition must be complemented by organizational pride. This constellation indicate that the process of influencing a group of people towards achieving organizational goals, and high appreciation for and a strong emotional attachment to the organization lead to job satisfaction.

It is worth noting that in these two constellations, the leadership style is an important and core factor by which employees achieve a high level of job satisfaction, so leadership behaviour of managers affect employee job satisfaction. Thus, the leadership style is a necessary (but insufficient) condition for high level of job satisfaction. High level of job satisfaction require the peripheral conditions associated with job satisfaction, namely work-life balance, rewards and organizational pride. The presence of satisfied employees as human resources in enterprises play great role and is very vital, that should be considered by managers of organizations. The success in achieving the organizational goals depends on the quality of human resources. Human resources in an organization occupy a critical position because it acts as the motor or driving force of an organization.

The results of research have practical implications for managers of SMEs, because they may provide them with a more holistic understanding of the factors that lead to job satisfaction. Use of fs/QCA is an original contribution to the wide range of research on job satisfaction, by studying the effect of all of selected conditions simultaneously and provide managers two constellations of conditions, affecting employee job satisfaction. Future research could replicate this study in other companies and countries or regions.

Improvisation as The Enhancer of Corporate Entrepreneurship

Przemysław ZBIEROWSKI

Abstract

The paper aims at investigating the influence of improvisation on corporate entrepreneurship, understood as entrepreneurial orientation. Intuitively improvisation is closely connected to EO, surprisingly, there is very little theoretical and empirical evidence on that relation. The paper aims at closing that gap by empirically investigating the role that improvisation plays in enhancing corporate entrepreneurship.
There is some empirical evidence on role of improvising in individual entrepreneurship (Hmieleski & Corbett, 2003; Baker, Miner & Eesley, 2003; Best & Gooderham, 2015). We use Hmieleski and Corbett's (2006) framework of improvisation as three-dimensional construct (creativity-bricolage, pressure-stress, action-persistence) and entrepreneurial orientation as three-dimensional (innovativeness, proactiveness, risk taking) construct to investigate the impact of improvisation on individual components of EO. The research has been carried out on a sample of 406 senior managers from medium and large organisations.
Improvisation has proven to have a moderate impact on entrepreneurial orientation. Moreover, different dimensions of improvisation influence components of EO in different way: creativity and bricolage have positive impact on innovativeness and proactiveness and pressure-stress has impact on propensity to take risk.
The study has implications for the theory of corporate entrepreneurship by highlighting possible antecedents of EO. Moreover, the results are significant for business practice as they provide useful ways of promoting corporate entrepreneurship.

Keywords: improvisation, corporate entrepreneurship, entrepreneurial orientation

Introduction

There are many ways in which entrepreneurs emerge from the society and start doing business. Some of them have a clear recognition of the opportunity and pursue it, some others are 'pushed' into entrepreneurship by external conditions. Some of them, however, have a special ability to create things out of existing limited resources – to improvise. That ability allows them to do things in a way that is different from the others – and sometimes that difference is sufficient to form a venture. Improvisation than has been proven to have a positive effect on the intention to become an entrepreneur (Hmieleski & Corbett, 2006). However, entrepreneurship is not limited to starting a business on one's own – corporate entrepreneurs can be as successful and in some settings more effective. What about them then – do they use improvising in their way to form a venture? are improvising employees and improvising companies more entrepreneurial? In this study I aim at answering those questions. The paper then aims at investigating the influence of improvisation on corporate entrepreneurship, understood as entrepreneurial orientation. Intuitively improvisation is closely connected to EO, surprisingly, there is very little theoretical and empirical evidence on that relation. My paper aims at closing that gap by empirically investigating the role that improvisation plays in enhancing corporate entrepreneurship.

Additionally, the paper concerns the role of environment in the relation between three dimensional construct of improvisation (creativity and bricolage, ability to function and excel under pressure-filled and stressful environments and spontaneity and persistence) and entrepreneurial orientation. I argue that the impact of the shape of environment (dynamism, hostility and complexity) is significant and the influence of improvisation on corporate entrepreneurship is even stronger in turbulent, resource-limited, complex and uncertain environments. The research was carried out within research project 2014/13/B/HS4/01618 funded by National Science Centre, Poland.

The nature of improvisation

Improvisation is defined as the creative and spontaneous process of attempting to achieve an objective in a new way (Vera & Crossan, 2003). Improvisation is by some authors used as an opposite for radical innovation (Ozgen & Minsky, 2016). I follow the view on improvisation presented by Hmieleski and Corbett (2006) and widely accepted in entrepreneurship research. According to them improvisation is a multi-stage process, in which at first an individual is presented with a problem Next, the individual compares the problem to others that he or she has previously faced and based on a past experience selects a referent – a plan or strategy for reacting to the problem. After identifying the referent, the individual considers its feasibility given the constraints that characterize the problem. If the referent is feasible and has a high probability of success, then it should be followed. Otherwise, the individual improvises by either extending or reconfiguring the referent to construct a novel course of action. This entire process occurs simultaneously, such that the individual is assessing probabilities and formulating strategy while acting out the solution.

Hmieleski and Corbett (2006) also present a coherent framework of improvisation composed of three dimensions: creativity and bricolage, ability to function and excel under pressure-filled and stressful environments and spontaneity and persistence. Creativity and bricolage represents the extent to which individuals are able to produce novel solutions under constrained conditions by recombining available resources. Individuals high in this dimension are likely to seek out opportunities to display their ingenuity. Ability to function and excel under pressure-filled and stressful environments represents the ability of individuals to excel in uncertain and rapidly changing environments. Individuals who are high in this dimension tend to rise to the occasion and perform best under pressure. Spontaneity and persistence represents the action orientation and determination of individuals toward achieving goals and solving problems in the moment. Individuals who are high in this dimension tend to prefer action rather than analysis and are highly focused on the problem at hand. These individuals are opportunistic and act with an instinct.

Hmieleski and Corbett (2006) confirmed the three-dimensional nature of improvisation using principal components confirmatory factor analysis. They also propose an aggregation of results in separate dimension to form a total score representing an individual's overall proclivity for improvisation. However, due to the differences in meaning of creativity and bricolage, ability to function and excel under pressure-filled and stressful environments and spontaneity and persistence I argue that they might be measured separately as components of multi-dimensional construct to provide more insight into the impact of improvisation on corporate entrepreneurship.

Improvisation as part of individual entrepreneurship

There is no evidence on the impact of improvisation on organisational level on entrepreneurial orientation. There is, however, some empirical evidence on role of improvising in individual entrepreneurship. Hmieleski and Corbett (2003) in their study of individual entrepreneurs challenge the paradigm of entrepreneurship research that considers the entrepreneurial process to be volitional, rational and linear. They argue that, due to various environmental constraints and cognitive limitations, the entrepreneurial process is often unplanned, non-rational, and circuitous and consider the role of improvisation in research focusing on entrepreneurial action. Later Hmieleski and Corbett (2006) claimed that improvisation can extend entrepreneurship theory by providing a framework for explaining how entrepreneurs deviate from both strategic plans and cognitive biases and heuristics in order to exploit opportunities in the moment, as they arise. They have proven that entrepreneurial intentions are significantly associated with measures of personality, motivation, cognitive style, social models, and improvisation, however, the strongest relationship is found between entrepreneurial intentions and improvisation.

Hmieleski and Corbett (2006) propose a framework of entrepreneurial action depending on the novelty of the situation and resource constraints of the individual or firm (Figure 1). When information and time are abundant, strategic planning is likely to be the choice. When time and information are both limited, but the entrepreneur has moderate knowledge of the problem or opportunity, then cognitive heuristics and biases are likely to be used. When resources are abundant, but the novelty of the situation is very high, the entrepreneur can afford to take a trial-and-error approach. When resource constraints are high and the entrepreneur is faced with a novel problem or opportunity, then improvisation appears to be the most best course of action. Constraints on time and resources do not allow for planning or trial-and-error, and the extreme novelty makes the use of heuristics and biases untenable.

		Resource constraints	
		Low	High
Novelty	High	Trial-and-error	Improvisation
	Low	Strategic planning	Heuristics and biases

Figure 1: Entrepreneurial action under varying degrees of novelty and resource constraints (Hmieleski & Corbett, 2006).

Hmieleski and Corbett (2008) conducted the study on moderating effect of entrepreneurial self-efficacy on the relationship of founders improvisational behaviour with performance of their start-ups and individual level of work satisfaction empirically. They prove that improvisational behaviour has a positive relationship with new venture performance (i.e., sales growth) when exhibited by founders who were high in entrepreneurial self-efficacy, but negative effect on new venture performance when exhibited by founders who were low in entrepreneurial self-efficacy. They also discovered that entrepreneurial self-efficacy has a negative moderating effect on the relationship between entrepreneur improvisational behaviour and work satisfaction.

Baker, Miner, and Eesley (2003) demonstrate that improvisation is often an elemental factor in the founding of new firms and that it is also useful in the exploitation of opportunity. The authors note, however, that their study was exploratory, inductive, and designed to focus only on generating hypotheses about improvisation and firm founding. Best and Gooderham (2015) on the other hand investigate improvisation as part of entrepreneurial behaviour.

Jahanmir (2016) in her study on the decision making styles of entrepreneurs, where she sets apart trade-off and paradoxical thinking, states that sometimes entrepreneurs are able to reconcile a contradiction of improvisation against planning, especially at later stages of venture creation. Some scholars also use improvisation as procedural trait of actions undertaken by entrepreneurs. Evers and O"Gorman (2011) claim that internationalization process is strongly influenced by two 'resources to hand': the entrepreneurs' idiosyncratic prior knowledge and their prior social and business ties and observed an effectuation logic and extensive improvisation in the internationalization process of new ventures.

The critical part of improvisation is bricolage which often is used by many authors as an independent variable, not being a part of a wider concept of improvisation. The concept of bricolage is also used referring to social bricolage to research entrepreneurship in specific forms and contexts, such as social entrepreneurship (Di Domenico, Haugh & Tracey, 2010) and arts entrepreneurship (Preece, 2014). The latter paper highlights the importance of six key elements for the success of bricolage, including: making do, a refusal to be constrained by limitations, improvisation, social value creation, stakeholder participation, and persuasion.

Improvisation on organisational level

Apart from the importance for entrepreneurs in forming new ventures, many scholars stress its role in organizational life. Davis, Eisenhardt and Bigham (2009) in their study exploring the tension between too little and too much structure that is shaped by the core trade-off between efficiency and flexibility in dynamic environments claim that a strategy of simple rules, which combines improvisation with low-to-moderately structured rules to execute a variety of opportunities, is viable in many environments but essential in some. They find that entrepreneurial organizations should quickly add structure in all environments, while established organizations are better off seeking predictable environments unless they can devote sufficient attention to managing a dissipative equilibrium of structure (i.e., edge of chaos) in unpredictable environments.

Linna (2013) in her study on significance of bricolage especially as a way to mobilize resources recognizes three different types of bricolage: a social mindset combined with resourcefulness; making do with resources at hand; and improvisation as way of proceeding. She argues that improvisation is an effective way of introducing innovation. Also Smets, Morris and Greenwood (2012) state that improvisations at work can generate institutional change by shifting field-level logic to focus on innovations.

Miner, Bassoff and Moorman (2001) indicate that improvisation can be accepted and incorporated into formal organizational activities, such that organizations may be able to plan for improvisation by creating opportunities for

improvisation and supporting the improvisation process. That view reconciles a contradiction between improvisational innovation and planned innovation that is suggested by some authors. Improvisation therefore might be use alongside other approaches of innovation to provide wider set of ideas for various circumstances.

All of the above views treat improvisation as an organizational activity. It means that improvisational activities are shared among employees and become a part of organisational culture and are further reinforced by the recruitment and selection of employees. Therefore, there arises the question on the impact of improvisation on some other organisational-level phenomena, such as corporate entrepreneurship and entrepreneurial orientation. To research this we treat entrepreneurial orientation as a three-dimensional construct (innovativeness, proactiveness and risk taking) as opposed to other forms of the construct with four or five dimensions (autonomy, aggressiveness). We also treat entrepreneurial orientation as multi-dimensional construct as opposed to uni-dimensional one. It means that we investigate each dimension separately instead of aggregating the results to a single score, although of course the dimensions are closely related.
The impact of improvisation on innovativeness is clearly apparent in above evidence – improvisation is a way to achieve innovations, so I hypothesise that:

H1. Improvisation has positive influence on innovativeness.

The relation between improvisation and proactiveness is less obvious and has not been a matter of empirical investigation and theorising. Proactiveness is opposed to reacting to competitors moves and is connected with gaining first-mover advantage. I argue that proactiveness is at the heart of improvisation. Although improvisation is by some authors used as an opposite for radical innovation (Ozgen & Minsky, 2016) which may result with higher proactiveness of radical innovators I argue that improvisation leads to outcomes that are different from those of radical innovation, but not necessarily less advanced. Therefore I hypothesise:

H2. Improvisation has positive influence on proactiveness.

Similarly to the above arguments, improvisation might be perceived as less risky than radical innovation. Moreover, there is evidence that improvisation demands less investments in risky activities than other forms of innovation. In that view, improvisation is a good way of balancing risk and innovating with low to medium level of risk. However, I argue that improvising organisations take more risk than those that neither improvise nor apply radical and other forms of innovation. Therefore I hypothesise:

H3. Improvisation has positive influence on risk taking.

Improvisation in unstable and resource-scarce environment

Existing literature on improvisation within organizations suggests that the critical element for the need and success of bricolage and improvising is the shape of the environment. More specifically, improvisation makes much more sense in unstable and resource-scarce environments than in stable and abundant ones. Hmieleski and Corbett (2006) criticise the view that entrepreneurship research should be centered around the process through which individuals identify and exploit opportunities to create future goods and services (Venkataraman, 1997) as a strategically planned sequence of opportunity identification followed by evaluation and execution. They claim that this model fails to fully elucidate how entrepreneurs behave within the highly uncertain, novel, and turbulent environments in which they often operate (Baron, 1998) and they support the notion of Baker, Miner and Eesley (2003) that those conditions are common throughout the entrepreneurial process. Linna (2013) argues that bricolage is especially effective as a method of innovation in a resource-scarce context. Smith and Blundel (2014) draw attention to the difference between established, big corporations and smaller entrepreneurial companies operating in unfriendly environments, especially in periods of economic crisis and instability. Authors argue that the typical strategy in those conditions is retrenchment and rationalisation designed to cut costs. Some firms adopt a more entrepreneurial approach, in which the key features are strategic reappraisal and various forms of product, process and organisational innovation. However, the differences in responses of big and small companies is in the nature of innovation. Big companies invest more money in risky activities while smaller companies use improvisation closely related to entrepreneurial bricolage as a means of accessing the resources required. As a result entrepreneurial companies are able to identify opportunities associated with new and expanding markets with scope for innovation. Those results are analogical to Linna's (2013) findings, but taken to organisational level. The importance of improvisation in uncertain and resource constrained environments is also highlighted by Häkkinen, Kannampuzha, Baker, Hmieleski, Honig, Miner, Powell & Sarasvathy (2016). They state that in the contemporary turbulent and constantly changing economic environments, it is difficult to predict the outcomes of an action and thus plan the societal, organizational end entrepreneurial goals beforehand. Also Vera and Crossan (2003) suggest six factors enhancing the effectiveness of improvisation: environmental turbulence,

experimental culture, real-time information and communication, memory, expertise, and teamwork skills, and Vera and Kachra (2004) develop a theoretical model of improvisational decision making as a new paradigm of how top management teams make decisions in fast-changing contexts.

Taking the above into consideration we formulate hypotheses on the combined impact on entrepreneurial orientation by improvisation and the environment that is turbulent, resource-limited and complex and uncertain:

H4: Environmental dynamism, hostility and complexity strengthen the impact of improvisation on entrepreneurial orientation.

Method, sample, variables and measures

To empirically test the above hypotheses I conducted a cross-sectional research on a random sample of 406 firms using CAPI technique by contracted research firm. In each of the firm senior manager was asked to answer the questions. The average time of one interview was 25,5 minutes. The methods of statistical analysis include reliability analysis, correlation analysis and regression analysis. Statistical analysis was carried out using SPSS software. For each of the dimensions of entrepreneurial orientation (innovativeness, proactiveness and risk taking) four regression models were tested. In the first one only control variables (size and age of the company) were placed as independent variables. In the second model only dimensions of improvisation (creativity and bricolage, ability to function and excel under pressure-filled and stressful environments and spontaneity and persistence) were placed as independent variables. In third model both control variables and dimensions of improvisation were independent variables and in the fourth model they were also supplemented with dimensions of external environment (dynamism, hostility and complexity).

As control variables were characterised by high skewness I decided to use natural logarithms of age (in years) and size (in number of employees) as control variables. Improvisation was measured by modified measure adapted from Hmieleski and Corbett (2006). Three items were used to measure each of the dimensions of improvisation: creativity and bricolage (α=.728), ability to function and excel under pressure-filled and stressful environments (α=.768) and spontaneity and persistence (α=.741). Entrepreneurial orientation was measured by eight-item Kreiser, Marino and Weaver (2002) scale. Three items measure innovativeness (α=.751), three measure proactiveness (α=.786) and two items measure propensity to take risk (α=.738). Environment dynamics was measured by two items (Naman & Slevin, 1993), environment hostility by two items (Green, Covin & Slevin, 2008) and environment complexity by one item (Miller, 1987).

Research results

The table below presents the means, standard deviations and correlations among the researched variables (Table 1).

Table 1: Means, standard deviations and correlations among the researched variables.

	Natural logarithm of age	Natural logarithm of size	Environment: complexity	Environment: hostility	Environment: dynamism	EO: risk taking	EO: proactiveness	EO: innovativeness	Improvisation: action-persistence	Improvisation: pressure-stress	Improvisation: creativity-bricolage
Mean	2.66	3.51	4.94	4.45	3.65	4.20	4.34	3.92	5.11	4.64	4.98
SD	.69	.88	1.35	1.30	.99	1.71	1.58	1.79	.80	.91	.92

Improvisation: action-persistence	-.068 .104	-.024 .574	**.097*** **.020**	.009 .827	.010 .814	**.191**** **.000**	**.178**** **.000**	**.159**** **.000**			
EO: innovativeness	-.055 .187	.045 .284	**.156**** **.000**	**-.092*** **.027**	**.122**** **.003**	**.206**** **.000**	**.438**** **.000**				
EO: proactiveness	-.048 .253	.079 .060	.107* .010	**-.139**** **.001**	-.019 .655	**.331**** **.000**					
EO: risk taking	-.025 .548	**.114**** **.007**	.043 .298	.014 .735	.071 .087						
Environment: dynamism	-.053 .205	.058 .165	**.123**** **.003**	.100* .016							
Environment: hostility	.045 .276	**-.094*** **.024**	**.297**** **.000**								
Environment: complexity	.056 .182	-.065 .121									
Natural logarithm of size	**.154**** **.000**										

The analysis of correlation suggests some very strong relations between all dimensions of improvisation and all dimensions of entrepreneurial orientation. Those results may be partly due to common method bias, nevertheless should be taken into consideration and confirmed in regression analysis. Individual dimensions of improvisation are also correlated to some of the variables concerning environment: creativity and bricolage with complexity, ability to function and excel under pressure-filled and stressful environments with hostility and spontaneity and persistence with complexity.

Table 2: Regression models with innovativeness as dependent variable.

	Innovativeness			
	Model 1	Model 2	Model 3	Model 4
Stable	3.965 .000	1.442 .005	1.448 .026	.914 .209
Natural logarithm of size	.110 .201		.136 .109	.110 .190
Natural logarithm of age	-.161 .143		-.169 .115	-.156 .140
Environment: dynamism				**.167** **.023**
Environment: hostility				**-.205** **.001**
Environment: complexity				**.209** **.000**

Improvisation: creativity-bricolage		**.440** **.000**	**.439** **.000**	**.371** **.000**
Improvisation: pressure-stress		-.078 .414	-.088 .362	-.031 .749
Improvisation: action-persistence		.127 .248	.132 .235	.117 .285
R^2	.006	.059	.064	.105
Adj. R^2	.002	.054	.055	.092
p	1.79	1.74	1.75	1.71

The explanatory power of all of the models of regression with innovativeness as dependent variable is rather low and below .1. The only dimension of improvisation that influences innovativeness is creativity and bricolage and the relation is highly statistically significant. Therefore, hypothesis H1 is partly supported. The last model achieves the adjusted R^2 much higher than other models. This proves that the shape of the environment plays an important role in the processes of improvisational innovation. However, the influence of environmental hostility is negative, so higher innovativeness is achieved with improvising in munificent environments, but at the same time complex and dyamic.

Table 3. Regression models with proactiveness as dependent variable

	Proactiveness			
	Model 1	Model 2	Model 3	Model 4
Stable	4.16 .000	1.94 .000	1.68 .003	2.20 .001
Natural logarithm of size	**.159** **.036**		**.183** **.014**	**.159** **.031**
Natural logarithm of age	-.146 .129		-.152 .105	-.150 .107
Environment: dynamism				-.051 .423
Environment: hostility				**-.224** **.000**
Environment: complexity				**.171** **.001**
Improvisation: creativity-bricolage		**.360** **.000**	**.399** **.000**	**.347** **.000**
Improvisation: pressure-stress		-.037 .660	-.083 .322	-.006 .942
Improvisation: action-persistence		.150 .120	.157 .104	.118 .217
R^2	.010	.062	.078	.113
Adj. R^2	.007	.057	.070	.101
p	1.57	1.53	1.52	1.50

Again, the only dimension of improvisation that influences proactiveness is creativity and bricolage and the relationship is highly statistically significant. Therefore, hypothesis H2 is partly supported. Similarly, the last model achieves explanatory power higher than the previous models (.101) which proves that the influence of environment is significant. In case of proactiveness as dependent variable two dimensions of environment are significant: hostility (negative effect) and complexity (positive effect). So similarly to innovativeness, improvisation has stronger effect on proactiveness in munificent but complex environments.

Table 4: Regression models with risk taking as dependent variable

	Risk taking			
	Model 1	Model 2	Model 3	Model 4
Stable	3.66 .000	.999 .039	.503 .408	.216 .756
Natural logarithm of size	**.233** **.004**		**.214** **.007**	**.211** **.009**
Natural logarithm of age	-.107 .305		-.089 .376	-.086 .396
Environment: dynamism				.068 .333
Environment: hostility				-.023 .690
Environment: complexity				.023 .670
Improvisation: creativity-bricolage		.178 .057	.191 .044	.185 .056
Improvisation: pressure-stress		**.378** **.000**	**.350** **.000**	**.351** **.000**
Improvisation: action-persistence		.109 .289	.118 .253	.127 .227
R^2	.015	.087	.099	.102
Adj. R^2	.011	.082	.091	.090
p	1.70	1.63	1.63	1.64

Results of regression analysis with risk taking as dependent variable are different from the other two dimensions of entrepreneurial orientation. First of all, the only dimension of improvisation that has impact on risk taking is the ability to function and excel under pressure-filled and stressful environments. Therefore, hypothesis H3 is partly supported. Secondly, the environment has no influence on the processes of improvisation and risk taking – the explanatory power of the fourth regression model is even lower than of the third model and none of the environment variables achieves statistical significance. Despite no impact of environment on improvisation-risk taking relation, it is significant with two other relationships, therefore, hypothesis H4 is partly supported.

Discussion

The conducted analyses bring some interesting results. First of all, there is a positive impact of improvisation on entrepreneurial orientation. That impact is manifested differently when it comes to individual dimensions of improvisation and entrepreneurial orientation, but is moderately strong and statistically significant. As assumed, creativity and bricolage has a strong effect on two dimensions of entrepreneurial orientation: innovativeness and proactiveness. That supports the theorising and empirical evidence of other authors stressing the role of improvisation in the process of innovation. What is important, the measure of creativity and bricolage focuses more on the process and the measure of innovation focuses more on the result. Therefore, bricolage really results in new products, services and processes being introduced. Moreover, it allows the companies that are improvising to be ahead of their competitors – pursue them aggressively and gain first-mover advantage. It shows that innovations created by improvising are not qualitatively lower than those created by radical innovation.

The dimension of improvisation that influences risk taking is ability to function and excel under pressure-filled and stressful environments. It is quite meaningful relationship – different aspect of improvisation results in higher willingness to take risk. It seems that even though regression analysis does not show universal relationships among all dimensions of improvisation and entrepreneurial orientation, those that exist point to individual components of improvisation resulting in individual components of entrepreneurial orientation, which supports the thesis that both constructs are multi-dimensional instead of uni-dimensional.

Finally, the significance of environment is quite apparent. Surprisingly, environmental hostility (related to resource scarcity) is negatively related to presented relationships. It means that improvisation creates higher results (in terms of innovativeness and proactiveness) in munificent environments and is contrary to previous findings. The component of environment that has positive effect on the relationship between improvisation and entrepreneurial orientation is environmental complexity. Uncertain conditions seem to favour improvisation as a way of introducing innovations. The component of entrepreneurial orientation that is not related to environment is risk taking.

Practical recommendations, contribution, limitations and future research directions

Research results provide a couple of recommendations for business practice. As Miner, Bassoff and Moorman (2001) suggest, improvisation can be incorporated and become a part of the formal structure of the organisation. It might also be planned and work alongside other forms of innovation to support them. Therefore, some activities should be undertaken by companies to foster improvising. Scarcity of resources could work as a trigger for those processes. Companies using improvising are able to achieve advantage, especially in a specific context. It should be considered though that improvising can be achieved at its highest level with a specific organizational structure and leadership style.

The study contributes to the discussion on the role of improvising in organisational processes, especially concerning innovations and corporate entrepreneurship despite having some limitations. One of them is simplified research model that is due to scarcity of empirical evidence in that regard. The study might be also laden with some bias, especially common method bias, therefore, future researchers in the field might consider using more fine-tuned measures and multi-source approach. It could be also fruitful to research some possible mediation/moderation with other variables, for instance leadership style or the effects of leadership style and organizational structure and culture, such as psychological empowerment (Spreitzer, 1995, 1996). Those kind of extended research models might yield some more interesting results. To gain even more insight into complex relationship between improvisation and entrepreneurial orientation it could be considered in future research to use a mixed method approach and enrich the empirical investigation with some qualitative techniques.

Aknowledgment

The research was carried out within research project 2017/27/B/HS4/02172 funded by National Science Centre, Poland.

Psychological Capital Cross-Over Effect

Milena GOJNY-ZBIEROWSKA

University of Economics in Katowice, Katowice, Poland
milena.gojny@ue.katowice.pl

Abstract

Psychological capital has proven to be a critical resource for employees desirable attitudes like satisfaction, commitment or well-being, desirable behaviours and performance. Furthermore, the PsyCap of followers benefits from PsyCap of leaders, however, despite some evidence, the conditions of that cross-over are largely unknown. This study explores the importance of three factors: age difference between leader and employee, leaders' age and organizational justice as moderators of the effect of leaders' PsyCap on followers' PsyCap. Using the data from random sample of 406 senior manager-direct subordinate dyads I confirm the PsyCap cross-over effect. Moreover, I find that the effect is stronger for older leaders and when the organizational justice is lower. The article concludes with practical implications and limitations of these findings and directions for future research.

Keywords: Psychological Capital, Organizational Justice, Leader, Age

Introduction

Psychological capital, or simply PsyCap, is known as predictor of desirable behaviours and attitudes. Previous research has proven that organizations benefit from high level of PsyCap of their leaders and followers. PsyCap is a useful predictor of important employee outcomes in the workplace like high productivity, low absenteeism, organizational citizenship behaviours, wellbeing etc. (e.g., Avey, Luthans & Jensen, 2009; Avey, Luthans & Mhatre, 2008; Luthans et al., 2007; Luthans et al., 2013; Avey, et al. 2011; Peterson et al. 2011; Youseff-Morgan & Luthans 2015). Investigations proved positive correlation of PsyCap with creative and innovative performance, innovation behaviour (Rego et al. 2012; Huang & Luthans, 2015; Özsungur 2020), performance (Baykal & Zehir, 2018; Peterson et al. 2011), then happiness (Williams, Kern & Waters, 2015). PsyCap is also negatively related to undesirable factors like turnover intention or stress (Avey, Luthans & Jensen 2009), cynicism, anxiety and deviance (Avey et al. 2011). Some studies exposes that PsyCap moderates and mediates relationships between others variables like authentic leadership and work engagement (Du Plessis & Boshoff, 2018), conveyed leader PsyCap and creative task performance (Avey, Richmond & Nixon, 2012) etc. PsyCap of workforce is crucial for organization because, as we know so far, crucial are the outcomes of it (Luthans & Youseff-Morgan, 2017). That is why recognising PsyCaps' antecedents, identifying causal processes related with PsyCap and boundary conditions for them is so important.

Some research has suggested that leadership may play a key role in developing follower PsyCap (Avey, Avolio & Luthans 2011). There is not much known about boundary conditions of this link. In literature was found just a couple investigations discussing this connection.

Extending existing studies, in current paper, drawn on social theories, is argued that between leader PsyCap and employee PsyCap exists significant relationship. In order to close the gaps mentioned above is further hypothesised that the linkage between leader PsyCap and employee PsyCap is moderated by age differences in leader and follower dyads, leader age and organizational justice. Research presented here makes a contribution to positive organizational behaviour by exploring PsyCap boundary conditions. This study has three objectives: (1) to re-examine the relationship between leaders' and followers' PsyCap; (2) to investigate how this relationship is moderated by organizational justice; and (3) to examine if the relationship between followers' and leaders' PsyCap is stronger when manager is older.

The research was carried out within research project 2017/27/B/HS4/02172 funded by National Science Centre, Poland.

Psychological Capital and its cross-over effect

It has been almost 15 years since PsyCap was introduced, defined and first measured in 2007 (Luthans et al. 2007). Since then there has been growing body of research on the field of PsyCap and much has been learned about it nevertheless still a lot remains unknown. Most of studies is focused on PsyCaps' outcomes. Leaders' PsyCap has been found to increase followers' PsyCap (Walumbwa et al. 2010; Chen, 2015). It has been also found that this relationship is mediated by the leader-member exchange (Story et.al. 2013; Chen et al.. 2019), followers' organizational (team) identification (Chen et al. 2017). Initial research indicated that this is trickle-down relationship and is moderated by follower self-esteem, the relationship is stronger for those with lower self-esteem (Avey, Richmond & Nixon, 2012). Second found study revealed that collectivism moderates the relationship between leader PsyCap and employee PsyCap such that the positive relationship becomes stronger when there is lower team collectivism and weaker when there is higher team collectivism (Xu, Liu & Chung, 2017). Meta-analysis indicated that job type, industry type and country culture may be moderators. Leaders' PsyCap influences their teams' PsyCap and followers' PsyCap can influence leaders' PsyCap (Haar et al. 2014).

The mechanism underlying correlation between PsyCap in dyads may be explained throughout a couples of theories. The most common concept evoking in the PsyCap literature is social learning theory. According to this theory employees learn from the role models by observing them (Bandura, 1977). In organization the role model is someone who has higher status than follower, someone who is respectful and also is influential source of knowledge to employees regarding what behaviour is appropriate, usually it is supervisor. Process of modelling explains the mechanism of seizing PsyCap from leader but is not exhaustive. In order to have more comprehensive view of the problem social identity theory and social exchange theory are often employed. According to classical meaning of identification (Kelman, 1961, p. 63) identification is based on the wish to gain the qualities of the other (e.g., Bandura & Walters, 1963). As identification very likely engender internalization of values and norms of group or other person, also attitudes and behaviour (Ashforth & Mael, 1989), employees' identity may absorb PsyCap of their leader. The social exchange approach assumes that benefits that employee derives from leader and organization through leader as the organizations' agent (Blau, 1964) may be the matter of trade in reciprocity chain or make this relationship stronger. Therefore in here social processes included social exchange theory, social identity theory and social learning theory are main justification for the process of transit PsyCap from leader to follower. This possibility is examined in this study and proposed is the following hypothesis:

Hypothesis 1: Leader psychological capital positively influences follower psychological capital.

Age has become an important factor in organisational research due to demographic changes in majority of countries. The analysis of the role of age in organizational studies revealed that age as a specific demographic trait variable might be significant. Age moderates some relationships within organizational behaviours for instance between procedural justice and turnover (Bal et a 2011) or between perception of procedural justice and long sickness absences (Tenhiala et al. 2013). It has been found also very strong moderation of an age on relationship between wage ratios and work valence, relative intrinsic value orientation, and relative autonomous regulation style (Stynen, Forrier, & Sels, 2014). Age as well moderates conditional indirect effect of HRM on work engagement via competence need satisfaction. This relationship is weaker for older employees while the conditional indirect effect of HRM on patient orientation via relatedness need satisfaction is stronger for older employees in hospitals (Gostautaite, Buciuniene & Milasauskiene, 2019). Age moderates the relationship between congruency in implicit and explicit motives and job satisfaction such that the relationship between i-e-congruency and job satisfaction is stronger for older as compared to younger workers (Thielgen et al. 2015). Another example of the age moderating role is its impact on relationship between task-specific self-efficacy beliefs and effort expenditure in organizational teamwork.

Leader older is often perceived as more experienced, wiser, more responsible and dependable then younger one (Spisak et al. 2014). That is why older leader should be better role model in a process of PsyCap modelling, and is also more likely a person that employee is willing to identify with. Moreover leaders' age should have positive impact on the transfer of PsyCap in a light of the reciprocity mechanism and social exchange theory. Research has shown that the age is positively related to the leader-member exchange (Gellert & Schalk, 2011). Leader might be more aware of their resources and trade process with an employee. Therefore exchange that creates rise of employees' PsyCap is stimulated by a leader more intense. All that lead to the second hypothesis:

Hypothesis 2: Leaders' age moderates relationship between leaders' and followers' PsyCap such that relationship will be stronger for dyads with older leaders.

In case of older follower age difference may be a reason to see the supervisor throughout father/mother lenses and treat them more paternalistic and forgiving and playing a bit of mentor role. Then for young leader it would be an

occasion to humbly derive from older follower expertize and wisdom. Leader may reciprocate with knowledge and psychological competences in which follower is lacking. In safe and accepting climate subordinate would be more willing to learn from younger. In such exchange PsyCap will be a part of the values and knowledge trade. This exchange is probable possible in dyads with significant age difference, where disparity is obvious and matches life roles. Similar, the bigger is age difference between leader and follower the strongest is impact of transformational leadership on teams' outcome [Kearney, 2008]. All that suggest that in dyads with older follower and younger leader the bigger age difference the better in terms of learning from each other and the impact leaders' PsyCap on followers' is collinear. Therefore third hypothesis assumes as following.

Hypothesis 3: The greater the age difference between leader and follower, the stronger the relationship between PsyCap of leader and follower.

Considering social exchange as the basis of the relationship between leaders' and followers' PsyCap we may expect that there are some organizational features that moderate this exchange. People compare their investment with pay-offs and its ratio to what get others (Festinger, 1954). In case of inequity followers are motivated to reduce what they provide and likely they lower their engagement. Perception of organizational justice is a key consequence of this assessment. Perceived organizational justice (POJ thereafter) refers to employees' perception of fairness in the workplace (Colquitt 2001; Moorman, 1991). POJ has been found to be associated with job satisfaction, organizational citizenship behaviour (Moorman, 1991; Cohen-Charash & Spector 2001), organizational commitment, performance and other positive organizational outcomes, employees' behaviours and job attitudes (Cohen-Charash & Spector 2001). POJ is also negatively related to retaliation behaviour like theft and sabotage, turnover and turnover intentions. (Skarlicki & Folger 1997). Perceived justice is one of the settings, boundary condition of relationship between despotic leadership, and narcissism and follower's sense of meaningful work (Kayani et al. 2020), between psychological empowerment and voice behaviour (Wei, Hisrich & Peng, 2020) and also between political skill and career success in the Chinese public sector (Lu & Guy, 2018). It has been also empirically demonstrated that POJ positively moderates the relationship between the human factor (which comprises of moral capital, human capital, and human capabilities) and perception of organizational effectiveness (Acquaah & Tukamushaba 2015). POJ also moderates the effect of learning stocks on organizational performance through feed-forward learning flows (Oh, 2019) and the strength of the relationship of abusive supervision with knowledge sharing mediated by emotional exhaustion, such that the mediated relationship is stronger under low POJ than under high (Lee, Kimb & Yunc 2018).

Follower feeling that is treated in a fairly way will appreciate it thus stronger will identify with leader and will be more engage in learning process, more eager to pay back in an exchange. Consequently the fourth hypothesis is:

Hypothesis 4: The relationship between psychological capital of leader and follower will be greater when the POJ is low then high.

Method: design, sample, variables and measures

To test the hypotheses and conceptual framework I carried out cross-sectional study on randomly selected sample of 406 enterprises and 812 respondents (dyads of leader-follower, one per organization). The data collection was carried out by using CAPI technique in Poland in April 2018. The approached organizations were of various industry and size, excluding micro-enterprises (up to 10 employees). The average age of the leader was 44.5 years and of the follower – 35.5 years. 50.7% or leaders and 49.8% or followers in the sample were women.

PsyCap was measured using Luthans, Youssef & Avolio (2007) measure consisting of 24 items. Cronbach's coefficients were at .946 for leaders and .952 for followers. POJ was measured using Colquitt's (2001) scale with 18 items (alpha at .973). As control variables I used leader's age, leader's and follower's tenure (in years), leader's and follower's gender, age and size of the enterprise. I have conducted separate regression analysis with follower's age as independent variable which showed that is has no relation to follower's PsyCap. The situation is similar for squared follower's age, which was taken into consideration to rule out the non-linear relationship between age and PsyCap.

Research Results

The results of correlation analysis (table 1) points to the possibility of existence of relationships between variables, especially between leader's PsyCap and follower's PsyCap. The correlation coefficients also suggest the multicollinearity between variables. The highest values for Variance Inflation Factor (VIF) were observed for leader's age, age difference and follower's tenure. However, the highest values are at the level of 2.8, it can be said therefore that multicollinearity is not inflating the results of regression analysis.

Table 1: Descriptive statistics and correlations between variables

		Mean	SD	1	2	3	4

In order to test the formulated hypotheses the hierarchical linear regression analysis was carried out. I tested three regression models with follower's PsyCap as dependent variable. In the first model (1) only the control variables were taken into account. In the second model (2) independent variable was added. Finally, in the third model (3) was tested the moderation effect by age difference between leader and follower, leader's age and POJ. For all of the models I have conducted the analysis of R^2 and adjusted R^2 coefficients, for models (2) and (3) I have also conducted the likelihood ration test comparing them to previous models (1) and (2) respectively. The results of regression analyses are presented in table 2.

Table 2: The results of regression analyses.

The decision to accept or reject certain hypotheses was based on the analysis of the levels of adjusted R^2 coefficient and results of likelihood ratio test. The regression analysis points to the fact that the effect of control variables is marginal and statistically non-significant. Conversely, there is very strong positive relationship between leader's and follower's PsyCap. Moreover, the adjusted R^2 coefficient for model 2 is at the level of 0.513 which shows high explanatory power of the model and strong effect of leader's PsyCap on follwer's PsyCap (confirmed by the likelihood ration test result). Therefore, the hypothesis 1 can be accepted.

The analysis of the third regression model brings results on the moderation of the relationship between leader's and follower's PsyCap by age difference, leader's age and POJ. The analysis of adjusted R^2 coefficient and likelihood ratio test shows that the third model achieves better model fit than the second model. Therefore, adding possible moderators to the model increases its explanatory power.

Research results show that age difference between the leader and the follower does not moderate the relationship between leader's and follower's PsyCap. Therefore, hypothesis 3 has to be rejected. There are, however, arguments to accept hypothesis 2 - the coefficient of the interaction between the age of the leader and leader's PsyCap is statistically significant. Figure 1 shows the graphical presentation of the moderation effect.

Figure 1: Moderation of the relationship between leader's PsyCap and follower's PsyCap by leader's age.

In the graphical presentation two values of the leader's age are shown – 35 and 55 years. There were taken as meaningful values that are the closest to the values set by the difference of 1 standard deviation from the mean value of leader's age (35.15; 53.85). Taking those values does not have an effect on the moderation results. For leader's PsyCap there are values taken according to established convention (+/- 1SD: 4.74; 6.26).

The moderation analysis shows that leader's age moderates the relationship between leader's and follower's PsyCap. The relationship is stronger for older leaders. The simple slope test shows that for the leaders at the age of 35 years the estimated value of the regression coefficient for leader's PsyCap is at the level of 0.626 and for the leaders at the age of 55 years is at the level of 0.868. Therefore, the relationship is significant for all leaders, however, for older leaders it is stronger than for the younger leaders.

The results of the third model of regression also point to the existence of the moderation effect by POJ. The statistical significance of the coefficient of the interaction between leader's PsyCap and POJ allows to accept hypothesis 4. Figure 1 shows the graphical presentation of this moderation effect.

Figure 2: Moderation of the relationship between leader's PsyCap and follower's PsyCap by POJ.

The graphical presentation of the moderation reveals the effect of justice that is also apparent in the regression results. In general, POJ supports the PsyCap of the follower. Moreover, it moderates the effect of PsyCap of the leader in a way that in low-perceived-justice conditions the effect is stronger. This means that the leader with high PsyCap is especially beneficial for the follower in organizations with low POJ. Simple slope test shows that in low justice (-1SD) the value of the estimated coefficient of leader's PsyCap is at the level of 0.703 and in high justice environment it is at the level of 0.385. It has to be said though that PsyCap of the follower reaches high levels in high justice conditions, and combination of high justice and high leader's PsyCap boosts follower's PsyCap to very high level.

Discussion

In reviewing literature there is an obvious lack of research of PsyCap boundary conditions, very little is known about what, how and why regulates relationship of PsyCap in leader-follower dyads. To address this gap, this study investigates three possible moderators. Statistical analysis supported hypothesis 1, confirming that leader PsyCap was positively related to follower PsyCap. PsyCap cross-over effect has been exposed in previous studies but this is the first research of this relationship in this cultural context, first in Poland. The strength of this relationship is high comparing to prior results. Coefficient was 0,75 comparing to 0,52 (Walumbwa et al. 2010), 0,45 (Story, 2013), 0,17 (Chen, 2015), 0,55 (Chen, 2017), 0,15 (Xu, Liu & Chung 2017) and 0,54 (Chen, 2019). It is only a brief matching of the coefficient factor without statistical analysis but it may signal that cultural context play a role since the less significant strength is in Asian cultures.

Second hypothesis was also confirmed. Leaders' age moderated relationship between leaders' and followers' PsyCap such that relationship was stronger for dyads with older leaders. It is consistent with previous research on older leader and carrier timetable theory. Older supervisor is more accepted as leader and is perceived as role model. PsyCap of older leader might be seen as more attractive and valuable and perceived as associated with wisdom. Apparently older supervisor has stronger impact on employees PsyCap with no regard to age difference between leader and employee. Thus third hypothesis is no supported. There is no evidence that with increase age difference the strength of the relationship between leaders' and followers' PsyCap will grow.

The last hypothesis assuming that POJ moderates the investigated relationship is supported. In prior studies POJ was found to enhance relationship of positive organisational factors with positive outcomes and weaken impact of negative features. Present research confirms positive role of perceived justice. The relationship between PsyCap of leader and follower is greater when POJ is low then high.

Earlier investigations have proofed follower self-esteem (Avey, Richmond & Nixon, 2012) then team collectivism (Xu, Liu & Chung 2017) to moderate the relationship between leaders and followers PsyCap. This research add to this short list also leaders age and POJ. All together gives the idea that the boundary conditions may be attached to organization, comes from supervisor or be an employee characteristic.

Limitations and future research

There are also some limitations that can be found in this study. The weakness that should be noted, is research design which is the cross-sectional data. That cannot provide evidence for causation and is subject of common method biases. The direction of the impact is assumed and it is based on prior investigations within the field. Thus longitudinal studies are recommended for the possible causal inference.

Following two weaknesses are associated with moderators. Perceived organizational justice is analysed as one variable. It would add much to the discussion if we analysed POJ effect through its dimensions. Furthermore, followers' age which was measured to verify the third hypothesis was applied without reflection on specific generational features and differences. Ones' own age perspective may be linked to the wider generational context.

As noticed for instance Luthans and Youssef-Morgan (2017) future research needs to take into consideration also cultural differences for a better understanding of how PsyCap may be transferred from leader to employee across cultures. Future research on psychological capital should aim to extend our knowledge about still missing boundary conditions and antecedents such as personality traits, perceived organizational support, trust, calling or thriving.

Acknowledgment

Abstract

Optimal allocation of distributed generations (DGs) is a well-known research area, being widely investigated in the last twenty-five years. In this paper, a modified honey bee optimization algorithm is considered to contribute to this research field area. Artificial Bee Colony (ABC) optimization is a recent metaheuristic based on the natural model of honey bee behavior in foraging for food. This algorithm is used in this to optimally allocate the cost required to connect a generation unit to a public distribution network. A case study, with two meshed IEEE 15-bus feeders and a new DG to connect, geographical dispersed, are used to simulate the performance of the proposed approach. The obtained results prove the effectiveness of the proposed approach to reduce the required charges for connecting new renewable generation units to electrical public systems. The result obtained show the efficient of the approach compared to PSO algorithm and sensitivity analysis based methods.

Keywords: Distributed generation, Connection cost, Optimal allocation.

Introduction

Distribution systems are usually designed as mesh networks, but operate as radial networks, it consists of two THE, Optimal allocation of distributed generations (DG) is a well-known area of research, widely studied over the past twenty-five years [1-2]. The problem of DG placement has attracted a great deal of attention [3], a wide range of solution methodologies for the location and sizing of active and reactive energy sources, and the detection of potential location and point of Optimal access for hosting DG sources has been presented in the literature.

Studies have shown that improper DG placement can increase total power losses [4], voltage deviation [5], operating costs [6], average system downtime [7] and can also have an impact on voltage stability [8], grid reliability [9] and almost any expected benefit from the installation of distributed generation in distribution networks.

Several methodologies have been presented in the literature with unique and multiple objectives for optimally distributing DGs in distribution networks.

Several objectives had been set to evaluate and optimize: location with specific capacity [10], size with defined location [11], combined location and size [12], type of DG [13], as well as the number of DGs [14]. The main objectives of the literature are the minimization of power losses [15], the improvement of the voltage profile [16], the improvement of the voltage stability [17], the minimization of costs [18], the maximization of profit [19], improvement of reliability [20], maximization of social welfare. [21], improvement of the index of average duration of interruption of the SAIDI system [22] and maximization of the distributed production capacity [23].

The mathematical formulation for the optimization of the site and the size of the DG in the literature is developed by modeling the electrical infrastructure and fixing the shape of the loads and the constraints of the network. The load model, distributed along the line [24] or concentrated on the network buses [25], the multiple load level [26], the variable load over time [27], the probabilistic loads [28] and fuzzy [29] are the types of load models presented in the literature. Bus voltage limits and infrastructure load limits, including lines and transformers, are the main constraints on the network.

In this paper, a modified honey bee optimization algorithm is considered to contribute to this research field area. Artificial Bee Colony (ABC) [30] optimization is a recent metaheuristic based on the natural model of honey bee behavior in foraging for food. The foraging process in bees is based on a very efficient movement mechanism. It allows them to draw the attention of other bees in the colony to the food sources found in order to collect various resources. In fact, bees use a set of wriggling dances as a means of communication between them. These dances allow bees to share information about the direction, distance, and amount of nectar with their fellows. Collaboration and collective knowledge of bees from the same colony is based on the exchange of information about the amount of nectar in the food source found by different members

A case study, with two meshed IEEE 15-bus feeders and a new DG to connect, geographical dispersed, are used to simulate the performance of the proposed approach.

The main-contributions of this paper:

1- First use of modified Honey Bee Optimization Algorithm in an optimal allocation of renewable distributed generation problem
2- Consideration of real cases of public distribution systems
3- Consideration of new optimization objective: connection cost reduction

The rest of this paper is organized as fellow: Section II presentation of Honey Bee Optimization Algorithm. Next in section III, presentation of the optimization problem. Section IV, the mathematic formulation of the problem. Section V, presents the case study with two meshed IEEE 15-bus feeders system. The result obtained are discussed in section VI. Section VII conclude this paper.

Honey Bee Optimization Algorithm:

In nature, several species are characterized by social behavior. Schools of fish, flocks of birds, and flocks of land animals are the result of the biological need that drives them to live in groups.

This behavior is also one of the main characteristics of social insects (bees, termites, ants…). From these principles, the researchers were inspired to develop methods based on the behaviors of these animals, and gave birth to what is called by Metaheuristics.

This word relates to all methods which model the interaction of agents (animals) which are able to self-organize. They represent combinatorial problem solving methods that consist of repeating certain processes until the optimal solution is obtained [32].

One of the most organized and rigorous insects in their work is the bee. Bees have a great capacity for communication. And thanks to his intelligence, a method called the bee method was developed. In this method, artificial bees represent agents which, by collaborating with each other, solve complex problems of combinatorial optimization.

Artificial Bee Colony (ABC)] optimization is a recent metaheuristic based on the natural model of honey bee behavior in foraging for food.

The foraging process in bees is based on a very efficient movement mechanism. It allows them to draw the attention of other bees in the colony to the food sources found in order to collect various resources. In fact, bees use a set of wriggling dances as a means of communication between them. These dances allow bees to share information about the direction, distance, and amount of nectar with their fellows. Collaboration and collective knowledge of bees from the same colony is based on the exchange of information about the amount of nectar in the food source found by different members.

In a bee colony optimization algorithm, a source of nectar corresponds to a possible solution to the problem at hand. The colony of artificial bees is made up of three types of bees: workers, spectators and scouts:

- The worker is exploiting the food source found. She bases herself on her memory and tries to make changes to her current position (solution) to discover a new position (i.e. food source).
- The spectator waits for the workers to return to the dance floor to observe their dances and gather information on the sources of nectar they have found.
- The Scout Bee exploits the research space by initiating a random search for a new food source.

In this algorithm, the location of the food source represents the possible solution to the problem, and the amount of nectar from that source corresponds to an objective value known as fitness.

Foragers are assigned to different food sources to maximize the total supply of nectar. The colony must optimize the overall efficiency of the collection. The distribution of bees is therefore a function of many factors such as the amount of nectar and the distance between the food source and the hive. This problem is similar to the distribution of web hosting servers, which was actually one of the first problems solved using bee algorithms by NAKRANI and TOVEY in 2004.

The number of active or inactive foragers represents the number of solutions in this population.

In the first step, the algorithm generates an initial population of randomly distributed SN solutions. Each solution x_ (i) (i = 1,2, ..., SN) that is initialized by the Girl Scouts, and represents a solution vector to the optimization problem. The variables that each vector contains must be optimized.

The active foragers search in the vicinity of the previous source x_ (i) for new sources v_ (i) having more nectar. They then calculate their fitness. In order to produce a new source of food from the old one, we use the expression opposite:

$$v_{ij} = x_{ij} + \phi_{ij}(x_{ij} - x_{kj}) \quad (1)$$

Where k∈ {1,2,…, BN} (BN is the number of active foragers) and j∈ {1,2,…, SN} are indices chosen at random. Although k is determined randomly, it must be different from i. ϕ_ij is a random number belonging to the interval [-1, 1], it controls the production of a food source in the neighborhood of x_ij.

After the discovery of each new food source v_ (ij), a greedy selection mechanism is adopted, i.e. this source is evaluated by the artificial bees, its performance is compared with that of 〖x〗 _ij. if the nectar of this source is equal or better than that of the previous source, this one is replaced by the new one. Otherwise the old one is kept [33].
For a minimization problem, Fitness is calculated according to this formula:

$$fit_i(\overrightarrow{x_i}) = \begin{cases} \frac{1}{1+f_i(\overrightarrow{x_i})} & si\ f_i(\overrightarrow{x_i}) \geq 0 \\ 1 + abs\left(f_i(\overrightarrow{x_i})\right) & si\ f_i(\overrightarrow{x_i}) > 0 \end{cases} \quad (2)$$

Such that $f_i(\overrightarrow{x_i})$is the value of the objective function of the solution $\overrightarrow{x_i}$

At this point, the inactive foragers and the scouts who are waiting within the hive. At the end of the search process, the active foragers share information about the nectar of food sources as well as their locations with the other bees via the wriggling dance. The latter evaluate this information taken from all the active foragers, and choose the food sources according to the probability value P_i associated with this source, and calculated by the following formula:

$$P_i = \frac{fit_i}{\sum_{n=1}^{SN} fit_n} \quad (3)$$

Where fit_i is the fitness of solution i, which is proportional to the amount of nectar from the food source in position i).

The food source whose nectar is abandoned by the bees, the Girl Scouts replace it with a new source. If during a predetermined number of cycles called a "limit" a position cannot be improved, then that food source is supposed to be abandoned.

All of these steps are summarized in the algorithm bellow:

Entry: S, W, O
Exit: the best solution

1- Initialize the population with S + W random solutions
2- Evaluate the fitness of the population
3- As long as the stop criterion is not satisfied, do
4- Recruit O inactive foragers and assign
5- each to a member of the population
6- For each inactive forager assigned to a member

7- n of the population do
8- Perform an iteration of the algorithm
9- search for new source
10- End for
11- Evaluate the fitness of the population
12- If a member of the population has not improved
13- during the iterations do
14- Save the solution and replace it with a
15- random solution
16- Find S random solutions and replace the S
17- members of the population who have poor fitness
18- End While
19- Return the best solution

Where S: number of scout foragers.
W: number of active foragers.
O: number of inactive foragers.

Distributed generation and connection costs

Several types of distributed production can be distinguished, depending on the technology, the type of generators used, and according to the primary energy they use, generally 2 main types of distributed production can be differentiated: conventional or traditional generators based on motors combustion, and Unconventional generator as: Storage devices, electrochemical devices and renewable device.

The distribution service is carrying out an orientation study to verify the feasibility of integrating the new DG, identifying and evaluating all possible options.

However, the efforts presented in the literature, to identify the optimal access point, are based on previous work in optimal seating and sizing of conventional generators and capacitor

Fig. 1: Flow chart of the proposed approach

banks, without taking into account that renewable DGs are different from others. devices, renewable generations are not presented in a compact form, with ease of installation and ease of transfer from one network substation to another network node. As in the case of photovoltaic generations, wind turbines or biomass units, DGs are developed over large areas, and the choice of DG site is influenced by several economic, climatic and geographic conditions. Surprisingly, no work had taken into account the geographic information of the network infrastructure and the DG site. However, changing the connection point, with a fixed DG site, means extending or shortening the total length of the electrical connection, which is paid for by DG owners, and which will clearly have an impact on their DG's total connection cost. to the network

Problem Formulation

$$F = \min(\mathrm{Cost}_{\mathrm{DG\ connection}}) \tag{4}$$

Subject to:
Voltage limits:

$$V_{L-\min} \leq V_x \leq V_{L-\max} \tag{5}$$

The bus voltage magnitudes are to be kept within acceptable operating limits throughout the optimization process. Thermal limits of lines and transformers:

$$J_{ij} \leq I_{Limit-max} \tag{6}$$

Power losses degradation:

$$P^{Before}_{total-Loss} - P^{after}_{Total-\ Loss} \geq 0 \tag{7}$$

Proposed Algorithm

The flow chart of the possible algorithm is given in figure 1.

Fig. 1: Flow chart of the proposed approach

Case study

The proposed analytical approach had been applied to the electrical system, presented in figure 2, composed of two meshed feeders of 15-buses, driven from two separate substations X and Y, and a new DG of 7600 kW to connect. The line data and load data of the electrical system are given in table 1, and distance from the DG unit seven possible connection-points are given in table 2.

Fig. 2: Single line diagram of the case study (Topology structure N°1)

Table 1: Load Data and Line Data of the two meshed feeders X and Y (feeder X and feeder Y are identical)

Table 2: Distance between possible connection-point and DG-site:

CB1	CB2	CB3	CB4	CB5	CB6	CB7
1471m	2501m	2156m	1550m	2155m	3016m	3188m

The proposed approach has been tested under the network topology reconfiguration. Figure 3 and figure 4 present the topology change.

Fig. 3: Single line diagram of topology N°2

Fig. 4: Single line diagram of topology N°3

The first step is the evaluation of the possible location of the DG unit. The results of the maximum and the minimum voltage magnitude for the three different topology structures are resumed in table 3.

Table 3: Evaluation of the seven connection-points with respect to the voltage profile under three different topology structures:

		Before DG	CB1	CB2	CB3	CB4	CB5	CB6	CB7
Fig 1	V_{max}	0.93	1.07	1.05	1.06	1.01	1.02	1.02	1.01
	V_{min}	0.92	1.01	1.01	1.01	0.99	1.04	0.98	0.97
Fig 2	V_{max}	0.98	1.04	1.04	1.03	1.04	1.02	1.07	1.04
	V_{min}	0.96	0.97	0.98	0.98	0.98	0.98	0.97	0.98
Fig 3	V_{max}	0.96	**1.11**	0.99	0.99	1.01	1.10	1.03	0.98
	V_{min}	0.93	0.98	0.98	0.97	0.97	0.96	0.93	0.95

By applying the proposed approach, the optimal size of D-FACTS is 135 kVAr at nodes “12X” and “13X”. The system performance after the connection of the renewable generation at connection point N°1, and the installation of the two D-Facts is given in table 4.

Table 4: Voltage profile before the connection of the new DG, after the connection at CB1, with and without the proposed method:

		Before the renewable generation	After the renewable generation at CB1	
			Without the proposed method	With the proposed method
Fig1	V_{max}	0,99	1,07	1,06
	V_{min}	0,98	1,01	1,02
Fig2	V_{max}	0,98	1,06	1,04
	V_{min}	0,93	0,97	0,98
Fig3	V_{max}	0,98	1,11	1,07
	V_{min}	0,93	1,00	1,00

By the application of the proposed approach the renewable generation could be installed at the connection pint N°1, with additional charges of installing and exploring two capacitors banks of 130 kVAr

Conclusion

In this paper heuristic optimization approach have been presented, based on the use a modified honey bee optimization algorithm. The results obtained prove the ability of the approach to reduce the cost required for the connection of generation unit in public medium voltage distribution systems.

Abstract

This paper proposes the implementation model of the multimodal freight transport development strategy in the TRITIA cross-border area. In the theoretical part the method of analysis and critical review of the literature was used. The literature researches confirmed that in the practice of the strategy implementation remains a huge gap between the process of formulating the strategy and its implementation. While there are undoubtedly many reasons behind the strategy's application gap, particular attention has been paid to the increasingly clear new challenges related to changes taking place in cross-border regions. Therefore, in the research part of the article, the authors made an attempt to develop a model for the implementation of the multimodal transport development strategy under the TRANS TRITIA project, hoping that the implementation of the project and recommended solutions will allow for better communication of the studied regions, the cross-border transport system will be unified and integrated, and it will also be possible to implementation of European recommendations contained in the White Paper on Transport in the area of alternative forms of freight transport.

Keywords: Model of Strategy Implementation, Multimodal Freight Transport, Cross-Border Area

Introduction

The dynamic development of international trade and the development of freight transport related to it, especially the road transport, prompts to seek the solutions that will counteract the negative effects of conducted transport activity. One of the solutions, promoted by the policy of the EU, is the multimodal transport. However, its popularisation requires developing and implementing a range of policies, strategies and activities conducted on the international, national and regional level. A special attention should be paid to the cross-border areas, located at the meeting points of various countries, often omitted in the analysis, at the same time generating a range of barriers that limit the development of formerly mentioned concept of transport. In relation to that, the authors undertook the problem of multimodal freight transport of Polish-Czech-Slovak cross-border areas (referred to as TRITIA) with the use of qualitative research. The goal of the paper is to present the implementation model of the multimodal freight transport development strategy in the indicated cross-border area. This strategy was created as a part of the work in international project entitled: "TRANS TRITIA – Improvement of coordination and planning of the freight transport in the region of the Trans Tritia project". It was implemented on the territory of four Central Europe regions: in the Silesia province, Opolskie province (Poland), in the Moravian-Silesian country (Czech Republic), and in the self-governing country of Žilina (Slovak Republic). The territory of the project covers over 34 thousand km2 and is inhabited by over 7 million people. Roads and transport corridors of the fundamental importance, including the Baltic-Adriatic transport corridor, run through the region of the project. The region of the project is closely related to the territory of the TRITIA European Grouping of Territorial Cooperation. It was established in order to improve and popularise international and interregional cross-border cooperation, between its participants, that aims at improving the economic and social cohesion, especially through the implementation of the territorial cooperation

projects. The developed strategy includes solutions that emerged in response to the identified problems and needs of the cross-border areas in terms of the multimodal transport development. It presents strategic and infrastructural projects necessary for the development of the cross-border freight transport and for the most effective switching from the road transport to the rail and inland waterway transport. That is why its implementation will allow to normalise and integrate the cross-border transport system and it will enable the implementation of European recommendations included in the White Paper of the Transport in the area of alternative branches of freight transport.

Strategy Implementation Models - Theoretical Background

Many authors share the opinion that there is a big discrepancy between the process of formulating the strategy and its implementation (Wołczek and Ignacy, 2017; Aleksander, 1991; Cândido and Morris, 2001; Hrebiniak, 2006). It is hard to assess the extent of this problem, however, according to the various sources, the implementation process ends in failure in 50-90% of the cases (Zook and Allen, 2001; Kaplan and Norton, 2005; Gendron, 1997; Carlopio and Harvey, 2012; Speculand, 2006; Desroches and Hatch, Lawson, 2014). The reasons for this state of things can be searched for due to the fact that the entities responsible for the implementation of the strategy do not have practical, but also theoretically strong models that would direct their activities during the implementation (Aleksander, 1991). The literature on the strategic management in the past years was concentrated mostly on the search for new ideas and tools for creating the strategy, at the same time neglecting the area of its implementation (Wołczek and Ignacy, 2017). Building the strategy implementation model is a hard and complex task due to the need to precisely capture the essence and the holistic context of the organisational implementation. Many managers think formulating and implementing a strategy are two distinct issues (Hrebiniak, 2006). Erica (2007) defines that the implementation is the process that turns strategies and plans into actions in order to accomplish strategic objectives and goals. Implementing the strategic plan is as important, or even more important, than the strategy. As Oskooee (2017) mentioned it, while strategies are most often developed by the board and stakeholders with great thought and care, implementation is often left to chance due to (Oskooee, 2017):

- leaders and managers feeling more comfortable with planning than implementation,
- leaders feeling that implementation is best left to someone else and that it is not their responsibility,
- implementation taking longer to accomplish and requiring adjustments as unforeseen circumstances occur and
- implementation requiring more people to be involved and continued communication over time.

G. Noga (2009) proposes characteristics of the strategy implementation models divided into three groups:

(1) the models concentrated only on naming and describing the implementation factors – in which the implementation consists of introducing change in all significant aspects of the organisation which need to be identified first. One of the models representing this group is the proposal of Peters, the so called model 7S. It indicates seven elements that are mutually related and a change in any of them results in change in the remaining ones. These elements are: strategy, systems, style, staff, value system, skills (Peters et al., 1980);
(2) the models of rational, sequential implementation process that take place in stages - they indicate the stages, more or less precisely, that should be followed in order to successfully implement the strategy, significantly changing the present situation of the organisation;
(3) the models which focus on the context and the process – they allow to understand and assess the complex transformational processes. In practical terms, the models as such help the managing staff and the managers of middle level to understand broader consequences of the change processes for the organisation, making them to concentrate not only on the specific part of the company, but also on the remaining functional areas, customers and competitors. One of the interesting models in this group is the the approach of F. Okumus. He proposed the implementation model (Fig. 1) consisting of four components: strategy content, strategy context, the process and the result (Okumus, 2003).

Key

a Changes in the external environment influence the strategic context and force organizations to deploy new initiatives.
b Problems and inconsistencies in the internal context require new initiatives.
c The strategy is implemented in the internal context, and the characteristics of organizational structure, culture and leadership influence the process factors.
d Having an organizational context that is receptive to change is essential for the successful implementation of strategy.
e The process factors are primarily used on a continuous basis to implement the strategy and manipulate the internal context.
f The characteristics of the context and process factors and how they are used directly influence the outcomes.

Fig. 1: Strategy implementation framework (Okumus 2003, p. 876)

Another approach to the classification of the strategy implementation models represent Cândido and Morris (2001), who make the division to:

(1) the static models that concern organisation in a given moment, identify, define and combine basic organisational dimensions for the effective implementation of the strategy. The authors propose twenty basic dimensions of the model presented as overlapping ellipses, highlighting this way the variety of dimensions which can be engaged in implementation of the strategy (Fig. 2);

Fig. 2: Synthesised static model – fundamental dimensions of strategy implementation (Cândido and Morris, 2001, p. 826)

(2) the dynamic models, sensitive to the resistance to changes, according to which the strategy implementation is performed along with sixteen isolated stages, however, some of them may be interrupted and continued later, or may appear several times in the iterative cycle, and some may overlap with others;
(3) the mixed models, integrated, including the assumptions of the static and dynamic models.

Another approach concerning the strategy implementation process is proposed by van Buul (2010) who divides the strategy implementation process to three phases: prepare, execute, assess. The prepare phase is initiated by the input from the strategy formulation process. After conducting the strategic analyses, which are the input to formulation of

the mission, vision, values and goals, the organisation is ready to start the preparation to an actual strategy implementation. Preparation of the strategy implementation is the key part of the implementation process, which mostly consists of developing the implementation plan, while its major parts include planning the implementation, mobilisation of the implementation team, assessment of the risk and creation of the emergency plans. After developing the implementation plan, the executive phase begins, which is the design and implementation of a new business model. After the implementation of the strategy, the new business model is being assessed in order to define whether it is compliant with the mission, vision, values, goals and strategic choices resulting from it. The necessary activity in the entire process of implementation is communication, the goal of which is to allow the employers to understand the new strategy and changes which they will have to deal with, as well as the coordination of the process that is needed in the entire implementation process, as to ensure that everyone does what is required for the effective implementation.

The proposed classification of the strategy implementation models was necessary to develop the multimodal freight transport development strategy model in the cross-border areas. It has to be emphasised that the developed model does not reflect the direct adopting of the specifically described model, rather, it is a combination of the presented ones.

Implementation Model of the Multimodal Transport Development Strategy in the Cross-Border Area

In accordance with the Strategy of Sustainable Transport Development (SZRT) by 2030 (SZRT by 2030) developed in Poland, the main goal of the national transport policy is to increase the territorial availability, to improve the safety of the traffic participants and the effectiveness of the transport sector by creating a cohesive, sustainable and participant friendly transport system in national (local), European and global dimension. The goal of the intermodal transport development strategy in cross-border areas developed as a part of the TRANS TRITIA project was not only the identification of the possibilities of developing a cohesive, sustainable, innovative and environmentally friendly transport system, but also the identification of the possibilities of increasing the transport availability by using the alternative, environmentally friendly transport in the border regions with simultaneous improvement of the efficiency and effectiveness of the transport processes.

Development of the multimodal transport development strategy in the cross-border TRITIA region first required the identification of the challenges faced by the entire analysed region, particularly in the context of the freight transport. Afterwards, the range of strategic analysis was conducted (including environmental and stakeholder analysis, SWOT analysis), that allowed to develop the vision, mission and to identify the main strategic goals for the multimodal transport development in the TRITIA region. Defining the main strategic assumptions became the basis for the development of the strategy implementation model, consisting of three main stages: prepare, execute and assess (Fig. 3).

Fig. 3: Implementation model of the multimodal transport development strategy in the cross-border TRITIA area (own study)

A fundamental stage of constructed implementation model is the preparation for implementation. This stage required defining the tools that will allow to implement in the next stages the implementation itself and to monitor and assess the level of implementation of the adopted strategy. To this end, it was proposed: Transport model for the TRITIA region, Balanced Scorecard and Action plans. Strategic scorecard allowed to develop the strategy map which includes specific goals allowing to implement the vision, mission and adopted main strategic goals. The second tool is the Transport model. In this model, an existing linear infrastructure (rail, road and inland) was mapped and current freight flows in TRITIA region were presented. The model was also used to present the predicted infrastructure state, including planned infrastructural investments on the transport network in perspective of the 2030. In compliance with the strategic goal of the White Paper of transport (2011) concerning shifting of the 30% of the freight transport on distances over 300 km from the road transport to other branches of transport, predicted volumes of the freight flows were presented in the model. Such mapping of the present and proposed state allowed to indicate the bottlenecks of the multimodal transport networks in perspective of 2030. On the basis of the transport model and strategy map, the projects of infrastructural nature, important for the multimodal transport development, were created. At the same time, apart from the infrastructural projects, it was necessary to indicate the projects of strategic nature that will allow for the implementation of the non-infrastructural strategic goals. This type of projects, concerning mostly the coordination of the processes and information flows between the stakeholders, are a very important factor of the multimodal transport development. At the next stage, the Action plans were developed for the infrastructural projects. They include a few pieces of information related to the implementation of the projects assumed in practice (mainly: owners of the projects, budget of the projects, time horizons of the project implementation). Indicated strategic projects, infrastructural ones and prepared Action plans, are subjected to implementation at the second stage of the strategy implementation (execute). At this stage, it is also necessary to finally clarify the information proposed in the former phase, included in the Action plans. Moreover, it is also crucial to constitute a developed organisational structure that both initiates implementation of the strategy and also participates in its monitoring process. As a part of the last stage (assess), the works related to the monitoring and assessment of the strategy implementation will be conducted. The assessment will mainly cover: the level of implementation assumed in the goal strategy map and information assumed at the stage of acceptance for implementation of the Action plans (mainly: project implementation schedule and planned budgets). The indicators proposed as a part of the BSC will be used in conducting the monitoring activities. Their results will constitute the feedback for both the entities implementing the strategy, as well as for the stakeholders of the multimodal transport.

It has to be emphasised, that implementation of the formulated strategy in accordance with presented model is of design and process nature. Implementation, as well as the former process of formulating the strategy, requires an adequate communication and coordination of the activities. The purpose of communication is to inform about the goals of the multimodal transport development in the cross-border area, implemented projects and results that are being obtained. Appropriate communication (meetings, workshops, information system etc.) will allow to develop good relationships with the stakeholders, create proper attitudes and behaviours, or build favourable image. Good communication is the basis for developing the coordination system based on the proposed organisational structure.

Adopted implementation model of the multimodal transport development strategy in the cross-border TRITIA region is currently at the last stage of the preparation phase. Some of the infrastructural projects are presently being implemented, the remaining adopted strategic assumptions are possible to implement in accordance with the developed model in the coming years.

Results and Discussion

Preparation of the strategy implementation

Conducted analyses in the cross-border TRITIA region led to formulation of the vision, mission and the strategic goals of the multimodal transport development in the indicated region. They are cohesive with the strong and weak sides indicated in the SWAT analysis, as well as with the opportunities and threats identified in the TRITIA region, and are fully compliant with the strategic assumptions of transport policy of the EU and specific countries (Slovakia, Czech Republic and Poland). These activities became the beginning of the implementation works of the developed strategic assumptions, in accordance with the model adopted in the point three of the paper.

The first stage of implementing the strategies in accordance with developed model is the preparation for implementation. In this phase, the strategy map created as a part of the Balance Scorecard (Blacha and Brzóska, 2016) was proposed. It allowed to transpose the formulated strategic assumptions to the measurable specific goals. As a part of the strategy map, the 24 goals were adopted which were included in six perspectives: development, infrastructure, process, safety and sustainable development, financial, stakeholders. In relation to the four classic perspectives indicated by Kaplan and Norton (1993), the adopted perspectives have been modified, considering the character of the region for which the strategy has been built. The perspective of the development has been modified, or rather clarified to safety and sustainable development perspective due to the meaning that is being assigned to the sustainable development in modern transport policy. This way, the meaning of the mentioned conception was emphasised and the adopted strategy has been entered into the assumptions of the White Paper. The second modified perspective concerns the clients. It has been modified into the stakeholders perspective. A change results from the big number and variety of the entities engaged in freight flows in cross-border multimodal transport. Due to that, it is impossible to narrow this group only to direct customers, however, it is necessary to consider other important groups that are related to this transport in a varying degree. Apart from the two changes in the perspectives, an additional infrastructure perspective has been formulated. It was the result of paying special attention to the technical aspects of the multimodal freight transport functioning, for which a very significant meaning have both the linear infrastructure in multi-branch approach, as well as the multimodal transshipment points. Two remaining perspectives did not require changes.

Considering the goals included in the strategy map and information about bottlenecks in the TRITIA region being the result of the works within the transport model, the projects concerning extension and modernisation of the transport infrastructure have been indicated. They were supplemented with projects of strategic nature that were the response to a part of the goals written in the strategy map, implementation of which requires not only the infrastructural activities, but also the organisational ones.

As a part of the projects of strategic nature, three projects (Table 1) have been proposed, for which a high priority for the multimodal transport development has been indicated. The meaning of these projects is visible, among others, by their strong relation with the goals written in the strategy map.

Table 1: Identified strategic projects

Name of the project	Goal of the project
Observatory of multimodal transport in the cross-border area (acronym: Observatory)	Constituting a specialised observatory which superior goal will be the identification and analysis of emerging technological and market trends related to the multimodal transport development in the TRITIA region.
Coordinator of the multimodal transport network (acronym: Coordinator)	Development of the multimodal transport network coordination model in the TRITIA region.
Competence centre for sustainable freight flows in the TRITIA region (acronym: Competence centre).	Designing the innovative service centres in the TRITIA regions, supporting the sustainable freight flows based on ecological transport branches and alternative sources of power,

Source: based on: Dohn et al. (2020)

The Observatory and Coordinator are the projects of key meaning for the implementation of the entire strategy. They were included in the monitoring processes, but they are also the organisations necessary for the synchronisation of the flows and unification of the multimodal transport system in the cross-border area, as well as for the future launching of the next projects that aim at the multimodal transport development. The Competence centre should provide support, which goal is to focus the activities on the research and development works in the area of alternative power sources and on the design of innovative centres network enabling supplying with alternative power sources. Each of the three indicated strategic projects includes several proposed detailed projects: The Observatory includes seven such projects, Coordinator – two projects, and the Competence centre three projects. It is important to bring attention to the relation between the first and second project. For an adequate implementation of the goals and indicated projects, it is necessary to implement the Observatory project first, and then the works in the Coordinator project should begin (it is not necessary for the first project to be finished before the second one starts). It results from the fact that the Observatory will be providing the results of the conducted observations to the Coordinator of the network. The third project is independent of the first two ones, thus, it can be implemented simultaneously with other projects.

Apart from the strategic projects, the projects of infrastructural nature have been identified as a part of the conducted research. They consist of commenced and not completed investments and planned (or predicted) investments that were included in the strategic documents and national infrastructure development programmes. Moreover, as a result of identification of the bottlenecks being the outcome of the works conducted in the Transport model, the projects have been proposed, that at the moment are not included in the strategic documents and their implementation is important for the multimodal transport development in the TRITIA region. All identified projects have been grouped according to: the transport branch (road, rail, inland waterway), cross-border area (Poland-Czech, Poland-Slovakia, Slovakia-Czech), priority (low, medium, high) and implementation time perspectives (short-term - by 2022, medium-term - by 2025, long-term - by 2030).

In first cross-border area Poland-Czech, a total number of 42 infrastructural projects has been identified. Their number, with consideration of the three main criteria, has been included in Table 2. It is worth noticing, that the highest priority has been assigned to 28 projects (66.67%) and the lowest priority has not been assigned to any implemented or planned to be implemented infrastructural projects. At the same time, it should be highlighted that all six projects indicated in the inland waterway transport have been considered as very important for the multimodal transport development (the highest priority). Considering the meaning of the inland waterway transport in the EU transport policy and the present low quality level of the waterways in Poland, it is a fully understood matter. Among the rail projects, the highest priority has been assigned to 19 projects (out of 23), and in relation to the road transport only three projects were given the highest priority. The small number of road projects of the highest priority results from the fact that according to the multimodal transport assumptions, the road transport is to implement only the delivery tasks from and to the transshipment terminals. It should be noticed, that 15 projects out of all the identified ones constitute the projects that aim to eliminate or limit occurring bottlenecks indicated at the stage of the linear infrastructure analysis and its implemented freight flows. 13 projects among them were given the highest priority. In case of the projects of medium priority, four ones were related to the rail transport, where two of them directly influence the bottleneck problem. The remaining ten projects were constituted by the projects that aim at the improvement of the road transport infrastructure. 15 projects (35.7%) were indicated as the projects of the shortest predicted implementation time, out of which 9 projects are the ones of the highest priority. The projects of medium predicted implementation time included 13 projects (31%) with 8 projects of the highest priority. The longest predicted implementation time concerns long-term projects. Their number totals 14 (33.3%), where 11 is of the highest priority.

Table 2: Consolidated view of the infrastructural projects in the cross-border area Poland-Czech Republic

Poland-Czech Republic cross-border area			
Number of projects in branch depiction	Rail transport	Inland waterway transport	Road transport
	23`	6`	13`
Number of projects according to the assigned priority	The highest priority	Medium priority	The lowest priority
	28`	14`	0`
Number of projects according the predicted implementation time	Short-term	Medium-term	Long-term
	15`	13`	14`

Source: own study.

In the second cross-border area Poland-Slovakia, the number of projects is significantly smaller and totals 25 projects. Their number, taking into account the three main criteria, is presented in Table 3. 14 projects (56%) is of the highest priority among all identified projects. Those are all rail projects and one road project. Only four rail projects were indicated as the ones that eliminate or limit the existing bottlenecks. 4 projects (16%) were indicated as the projects of the shortest predicted implementation time, out of which only one project was of the highest priority. 9 (36%) projects were indicated as the projects of medium implementation time and seven of them were given the highest priority. 12 projects (48%) were indicated as the projects of the longest predicted implementation time, out of which 6 projects are the ones of the highest priority.

Table 3: Consolidated view of the infrastructural projects in cross-border area Poland-Slovakia

Poland-Slovakia cross-border area			
Number of projects in branch approach	Rail transport	Inland waterway transport	Road transport
	13`	0`	12`
Number of projects according to the assigned priority	The highest priority	Medium priority	The lowest priority
	14`	11`	0`
Number of projects according the the predicted implementation time	Short-term	Medium-term	Long-term
	4`	9`	12`

Source: own study.

In the third cross-border area Czech-Slovakia, the number of projects is significantly smaller and totals 11 projects. Their number, with consideration of the three main criteria, has been included in Table 4. It is typical that all the rail projects have the highest priority and the road projects a medium priority. The projects of the shortest implementation time included four projects (36.4%) and only two of them were of the highest priority. All the projects of a medium implementation time are characterised by the highest priority. The projects of the longest predicted implementation time mostly concern the projects of a medium priority (three projects).

Table 4: Consolidated view of the infrastructural projects in cross-border area Czech Republic-Slovakia

Czech Republic-Slovakia cross-border area			
Number of projects in branch approach	Rail transport	Inland waterway transport	Road transport
	6`	0`	5`
Number of projects according to the assigned priority	The highest priority	Medium priority	The lowest priority
	6`	5`	0`
Number of projects according to the predicted implementation time	Short-term	Medium-term	Long-term
	4`	3`	4`

Source: own study.

Identified infrastructural projects were detailed as a part of the Action plans. For each of the project, the owner responsible for its implementation was proposed, predicted funding sources were determined and estimative budgets were presented. The directors of the transport infrastructure (rail, road, inland waterway) were indicated as the main infrastructural projects owners in specific countries. Among the 9 main owners, the following can be indicated: PKP PLK SA, Železnice Slovenskej Republiky (Railways of the Slovak Republic), Správa železnic, s.o. (Czech railway infrastructure manager), Generalna Dyrekcja Dróg Krajowych i Autostrad (General Director for National Roads and Motorway), Ředitelství silnic a dálnic, Národná diaľničná spločnosť, Ministry of Marine Economy and Inland Navigation, Polish Waters Holding, ŘVC and Moravskoslezský kraj. In case of strategic projects, the EGTC TRITIA was proposed as the entity responsible for their implementation, along with the partnership of the business environment institutions (GAPR Sp. z o.o.) and science centres (Silesian University of Technology, research and development institutes from the Czech Republic and Slovakia). In the Action plan it was also attempted to define the projects budgets and to indicate their financing sources. Basic sources of funds for the investments consist of the rail programmes. However, the anticipated scale of expenditure is so large that it can be assumed that the EU funds will need to participate.

Strategy Implementation – Execute and Assess

The projects adopted at the stage of preparation to implementation and the Action plans will be implemented at the second stage of the strategy implementation. It is important that at this stage the final information assumed in the Action plans is clarified. Moreover, it is necessary to constitute and approve the organisational structure (Fig. 4) that includes the most important entities influencing the success of the implementation process. Organisational structure not only initiates the strategy implementation process, but it also has a key meaning in the process of monitoring and assessing the level of implementation.

Fig. 4: Organisational structure of the implementation strategy of the multimodal transport development (Dohn et al., 2020).

The organ responsible for the implementation of the strategy will be the EGTC TRITIA. Most of all, this responsibility will concern building and development of the multimodal transport ecosystem in the TRITIA region, as well as reporting in terms of the level of implemented actions. The key element of the structure is the assumption

of implementation of three strategic projects (Observatory, Coordinator, Competence centre), within which the indicators of the strategy will be reported and monitored. The decision-making and advisory organ for the matters related to strategy implementation and programming, coordination, implementation, monitoring and evaluation of the multimodal transport development policy in the TRITIA region will be the Steering Committee, bringing together the key governmental and self-governmental organisations of the Czech Republic, Poland and Slovakia. The activities of the Steering Committee will be supported by the Stakeholder Council which goal is to undertake substantive works on the main tasks resulting from the present needs of the TRITIA in terms of the multimodal transport development. Presentation of the expertises and reports at the Steering Committee meeting will be the result of its works. Relationships between main entities (investors), universities and associations that have the key impact on the multimodal transport development, have a significant meaning in terms of cooperation between the CoS and the EGTC TRITIA, and constituted Observatory, Coordinator and Competence centre. Implementation of the tasks in terms of monitoring and evaluation will be based on the present EGTC TRITIA structure, with the support of the Steering Committee for the multimodal transport development. Monitoring will include implementation of the projects in the TRITIA region and indicators that will allow to verify the implementation level of the goals adopted within the strategy map. The indicators were adopted separately for each goal as a part of the six perspectives of the strategy map. In the paper, only an exemplary ones will be included, presented in a consolidated way for each of the perspective separately.

Table 5: Examples of the strategy implementation monitoring indicators

Perspective	Number of indicators	Examples of indicators
Stakeholders	9`	- Average delay time in multimodal transport - Percentage share of the multimodal transport in the total structure of freight flows in the TRITIA area - Number of programs aimed at strengthening cooperation in networks and supply chains - Number and scope of agreements between countries (Poland, the Czech Republic, Slovakia) aimed at unifying policies in the implementation of material flows in the TRITIA area - The level of subsidy of tax reliefs for the use of multimodal transport
Financial	6`	- Number of projects acquired in the field of multimodal transport development in the TRITIA area - Number of investors in the development of multimodal transport - Number of initiatives undertaken to raise funds for the development of multimodal transport
Safety and sustainable development	4`	- Number of projects aimed at increasing the safety of multimodal freight transport in the TRITIA area - The level of external costs in freight transport
Process	12`	- Number of multimodal transport support programs for enterprises from the TSL industry - Number of standardised procedures in multimodal transport in the TRITIA area - Number of implemented modern organisational solutions in multimodal transport - Number of participants in the multimodal transport chain supported

Source: own study.

In the strategy, 58 indicators were proposed for monitoring and evaluation of the strategy implementation. However, the list remains open. There is a possibility of supplementing the list with additional important indicators.

Moreover, in order to conduct monitoring and evaluation activities, the sources of acquiring information for determining the indicators were presented. It should be noticed, that presently there are deficiencies in terms of gathering some information required for conducting an effective monitoring. Due to this, there is a necessity of building a complete system of acquiring and gathering information. It is a necessary condition for conducting monitoring activities.

Conclusions

The developed model of implementing the multimodal freight transport development strategy is the tool that supports the activities aiming at the dynamic increase of the multimodal transport in the cross-border areas of Poland, Czech Republic and Slovakia. In order for this to happen, it is necessary to engage all participants of the process, that is all mentioned countries and various groups of stakeholders. It is necessary to create favourable conditions for cooperation and common implementation of the projects in the infrastructure development region and organisational support. A challenge for implementation of the developed strategy is to eliminate the delays in development, modernisation and revitalisation of the transport infrastructure, as well as connecting the most important nodes of the European transport network, including TEN-T base corridors. A cohesive network of highways, expressways and railway of high standard, as well as created network of inland waterways, will allow to fully use the economic potential of the three analysed countries. It has to be remembered that creation of the cohesive multimodal transport ecosystem requires both dynamic development of lacking elements of the transport infrastructure, improvement of its quality and technical standards, as well as introducing the solutions that integrate transport networks.

A success of the strategy implementation is strongly dependent on constituting the Observatory and Coordinator as entities proposed within the strategic projects. At the same time, it is also a characteristic that distinguishes this approach and creates its authenticity, however, it should be also perceived as the main risk. If it will not be possible to constitute the Observatory and Coordinator in assumed time, the designed organisational structure will not be able to effectively perform the entire strategy implementation process. Strategy implementation is based on the design and process approach. The key role, next to the mentioned strategic and infrastructural projects, belongs to the communication and coordination process that not only influences the implementation of strategic goals, but also the creation of appropriate attitudes that facilitate cooperation necessary for the implementation of assumed activities, characteristic for the multimodal transport.

The authors of this strategy are convinced that the implementation of its assumptions will contribute to the development of modern transport system on the cross-border areas included in the projects, and it will also constitute the element of a broader context for the transport system development in the entire European Union.

Subsequent studies on the implementation of the strategy, and especially its vision, will be related to the analysis of stakeholders in the multimodal transport ecosystem.

Abstract

Well-being of employees is largely dependent on behaviors of leaders. But does it matter for the happiness of followers if the leader is happy as well? And do happy leaders behave differently towards their subordinates than unhappy ones? In this study we make an attempt to unpack the mechanism of cross-over of well-being from the leader to the follower. Specifically, we consider both direct relationship involving emotional contagion and indirect relationship mediated by perceived support and empowerment. Using the responses from 406 leader-follower dyads we find that the well-being cross-over effect is both direct and indirect. Moreover, we find that behavior of the leader are strongly dependent on level of well-being. Happy leaders are more supportive towards their followers and more likely to give away some of the power.

Keywords: leader's well-being; follower's well-being; well-being cross-over effect; social support; empowerment

Introduction

Well-being of employees as an outcome of behaviors of the leader has been a matter of intense scholarly investigation (Inceoglu et al., 2018). It has been found mainly related to specific leadership styles, such as transformational leadership (Nielsen et al., 2008) or authentic leadership (Ilies et al., 2005). However, few studies considered the cross-over effect of well-being from the leader to the follower and its underlying mechamism (Skakon et al., 2010). The existence of such cross-over effects has been proven in relation to some well-being-related outcomes, such as emotional exhaustion and work engagement (Wirtz et al., 2017), job dissatisfaction (Sutherland & Davidson, 1989) or burnout (Ten Brummelhuis et al., 2013; Huang et al., 2014). Moreover, while there is evidence on the effect of specific leadership styles on both follower's (see e.g. Inceloglu et al., 2020 for a review) and leader's well-being (Ilies et al., 2005), little is known about the dependence of certain leadership behaviors and style on the level of leader's well-being. Therefore, in this study we ask the question of how happiness changes the way in which the leader behaves, and how is that conveyed to happiness of followers, both directly and indirectly. More specifically, we investigate the direct effect of leader's well-being as well as indirect effect mediated by support given to the follower and the extend to which the follower is empowered by the leader.

We contribute to the body of literature on leader's behaviors and well-being. We contribute by reversing the question on the effect of leadership style on well-being. Instead of asking what is the effect of certain leader's behaviors on leader's well-being (Ilies et al., 2005, Bernerth & Hirschfeld, 2016; Kaluza et al., 2020) we ask and investigate how are leader's behaviors driven by the level of leader's well-being. We also further unpack the mechamism by which the well-being of the leader is crossed-over to the well-being of the follower. We point to relational leadership styles: supportive and empowering as mediators and empirically prove that they play important role in the well-being cross-over effect. The research was carried out within research project 2017/27/B/HS4/02172 funded by National Science Centre, Poland.

Theoretical background

Our theoretical framework, firstly, considers the cross-over effect between the leader's and the follower's well-being. We focus on well-being in a broader sense than just satisfaction with work, and take into consideration satisfaction with life. The existence of cross-over effect of well-being related states from the leader to the follower has been proven before (Ten Brummelhuis et al., 2013; Huang et al., 2014; Köppe et al., 2018). The mechamism of that effect

Cite this Article as: Przemysław ZBIEROWSKI and Milena GOJNY-ZBIEROWSKA "Leader-Follower Well-Being Cross-Over Effect Mediated By Leadership Style" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

is, however, still largely unknown. The two competing hypotheses explain this effect either by the transfer of emotions from the leader to the follower (affective cross-over) or due to specific behaviors of the leader (behavioral cross-over). There is some empirical support for the direct hypothesis of emotional contagion (Ten Brummelhuis et al., 2013), therefore we hypothesize:

H1. Well-being of the leader has direct effect on the well-being of the follower.

We argue that the transition of well-being of the leader to the well-being of the follower is only partly direct and based on mechanisms such as emotional contagion (Köppe et al., 2018). We further argue that the other part of the cross-over effect of well-being of the leader to that of the follower is transferred through specific type of leader's behaviors, especially relationship-oriented behaviors and leadership style (Yukl et al., 2002; DeRue, 2011), such as supportive leadership or empowering leadership (Inceoglu et al., 2018).

We adopt the understanding of supportive leadership based on House's (1981) approach which combines emotional, informational, instrumental and appraisal support to followers. Instead of paying attention to leader's behaviors we approach (and measure) supportive leadership by the support actually received by the follower. This way we are able to capture not just the leader's behavior but the outcome that this behavior intends to achieve. For that reason we use perceived organizational support (Eisenberger et al., 1986) as our mediator between well-being of the leader and that of the follower.

There is evidence that leader's own well-being is linked the supportive behaviors. Maurya and Agarwal (2015) found that followers are satisfied with their jobs if their leaders supportive behaviors are linked to leaders' well-being. Ten Brummelhuis et al. (2013) argue that leader's burnout is negatively related to leader's supportive behaviors. We therefore theorize that higher level of leader's well-being will be beneficial for the support that is provided by the leader to the follower.

The effect of support received from the leader on follower's well-being has been of particular interest in the occupational stress field (e.g. Cohen & Wills, 1985; Kahn & Byosiere, 1992). The research in that field describes two models explaining the effect of social support on well-being of employee. The 'buffering hypothesis' argues that social support affects well-being mainly when the receipient of the support is likely to experience high level of stress. In this case the support protects the receipient from the potentially negative influence of stressful event. The 'main effect' model proposes that social support has positive effect on well-being of the receipient of support regardless of the experienced stress (Rafferty & Griffin, 2006). The positive effect of received support on follower's well-being has been also supported by others (e.g. Schmidt et al., 2014; Ceasens et al., 2016; Kim & Beehr, 2018; Skakon et al., 2010 for a review). Together with the hypothesized effect of the leader's well-being on supportive behaviors we hypothesized that:

H2. Support received by the follower mediates the relationship between leader's and follower's well-being.

Psychological empowerment in its most prevalent conceptualization (Spreitzer, 1995; 1996) is composed of four cognitions reflecting an individual's orientation to his ore her work role: meaning, competence (self-efficacy), self-determination, and impact. Srivastava et al. (2006) make an attempt to integrate the two perspectives of empowering leadership. The first focuses on leader's behaviors, especially sharing power or giving more responsibility and autonomy to followers. The second perspective focuses on outcomes of empowering leadership among followers. We follow that integrative view and link the leader's well-being to empowering behaviors which, in turn, enhance psychological empowerment of employees.

Similarly to supportive leadership there is very little evidence on dependence of empowering leader's behaviors on level of well-being. Chi et al. (2011) argue that happy leaders are more transformational, a view also echoed by Joseph et al. (2015). As transformational leadership has been found to result in high follower's empowerment (Kark et al., 2003) we argue that this type of leadership is, in fact, empowering and that leaders well-being is positively related to empowering subordinates.

The effect of leader's empowering behaviors on follower's well-being is rather well-documented (Tuckey et al., 2012; Skakon et al., 2010 for a review). Therefore, we hypothesize that:

H3. Empowerment of the follower mediates the relationship between leader's and follower's well-being.

The result of our theorizing is the conceptual framework that assumes the existence of both direct and indirect cross-over effect of well-being from the leader to the follower (Figure 1).

Figure 1: Conceptual framework of leader-follower well-being cross-over effects.

Methodology

To test our hypotheses we collected the data using multi-source approach from 406 dyads of leaders and followers. The sample was randomly chosen among small, medium and large organizations with the exclusion of micro-enterprises, as leader-follower relations in those kind of organizations most often involve the owner of the business.

We use the Satisfaction with Life Scale (5-item, Pavot & Diener, 2008) to measure well-being of the leaders (Cronbach alpha .83) and followers (Cronbach alpha .85). To measure follower's perceived organizational support we use the Survey of Perceived Organizational Support (13-item, Eisenberger et al., 1986, Cronbach alpha .78). Finally, we use Spreitzer's (1995) scale to measure empowerment of followers (12-item, Cronbach alpha .86). We control for leader's and follower's age, gender and tenure.

We test our hypotheses using structural equations modeling, we use SEM module of Stata software.

Results

First, we test the model with only leader's well-being as independent variable and control variables (without supportive and empowering leadership). The results are presented as model (Table 1). The relationship between leader's and follower's well-being is rather strong and statistically significant.

Table 1: Results of structural equations modeling

	(1)	(2)	(2)	(2)

	(0.00754)	(0.00614)	(0.00542)	(0.00659)
Constant	2.801***	0.248	3.293***	2.624***
	(0.418)	(0.387)	(0.301)	(0.366)
Observations	406	406	406	406

*Note. Standard errors in parentheses, *** p<0.001, ** p<0.01, * p<0.05, † p<0.1. POS – perceived organizational suport, WB – well-being*

To test the hypotheses we test the model 2 which is our conceptual framework. The results indicate that with the inclusion of POS and empowerment the direct relationship between leader's and follower's well-being is weakened, but still statistically significant (Figure 2). This proves the existence of direct relationship and supports H1. Also the indirect effects with the mediation by perceived organizational support and empowerment are statistically significant which provides support for hypotheses H2 and H3.

Figure 2: Conceptual framework of leader-follower well-being cross-over effects.

As robustness checks we tested the models with only perceived organizational support and only empowerment as mediators in the relationship between well-being of the leader and the follower. When empowerment was removed from the model the direct relationship and indirect relationship (mediated by POS) were both significant (.2, p<.001; .18, p<.001, respectively). When POS was removed from the model the direct relationship and indirect relationship (mediated by empowerment) were both significant (.16, p<.001; .22, p<.001, respectively).

Discussion and Implications

First of all, we confirm the hypothesized cross-over effect of well-being from the leader to the follower. This corroborates earlier findings in relation to other well-being-related constructs (Sutherland & Davidson, 1989; Ten Brummelhuis et al., 2013; Huang et al., 2014; Wirtz et al., 2017). We can then state that happiness of the leaders tends to spread to followers. We further unpack the mechamism of such cross-over effect and conclude that it is partly due to affective cross-over or emotional contagion. Leaders influence followers and this is also true for well-being. Spending considerable time with another person results in contagion of emotions.

We also found that majority of the cross-over effect is indirect and mediated by certain leadership behaviors resulting in certain follower's outcomes, such as perceived organizational support and empowerment. It seems that those two styles of leadership, and their consequences are reinforcing themselves, their combination is beneficial for well-being and performance of employees (Butts et al., 2009).

An important implication of our study is the support for the hypothesized relationship between well-being of the leader and supportive and empowering leadership styles. This proves that happy leaders are more inclined to give support and power to their followers. This finding is important as earlier studies almost exclusively focused on well-being of employees and very few that took into consideration well-being of the leader used it as dependent variable. We uncover that leader's happiness might be an important resource in leading employees (Chi et al., 2011; Joseph et al., 2015).

Our study unpacks the mechanism of well-being cross-over effect, however, one piece that might be still missing is the relationship between leader's well-being and perceived support and empowerment of followers. Therefore, future studies should consider additional variables related to leader's behaviors and employ more sophisticated research methods such as diary studies.

Aknowledgment

The research was carried out within research project 2017/27/B/HS4/02172 funded by National Science Centre, Poland.

Green Marketing as a Tool for Building the Corporate Reputation as a Socially Responsible Organization – Critical Approach

Danuta SZWAJCA

Silesian University of Technology, Faculty of Organization and Management, Zabrze, Poland,
E-mail: danuta.szwajca@polsl.pl

Abstract

Enterprises are trying to build their reputation as socially responsible organizations due to the growing environmental awareness of consumers and the pressure of other stakeholder groups on corporate social involvement. To this end, they use the concept and tools of green marketing. It turns out, however, that many companies only use green marketing tools to create the desired green image, not reputation. In many cases, this leads to manipulation and simulation of pro-ecological and pro-social activities, i.e. greenwashing, which is counterproductive when it comes to building a "green" reputation. The article presents the importance of green marketing in building the company's reputation as a socially responsible organization, indicating the negative effects of greenwashing practices, and proposes methods of using green marketing that give companies the chance to build the desired reputation more effectively. The research methodology was based on a critical analysis of the literature, a thematic review of research results and deductive inference.

Keywords: Green Marketing, Corporate Reputation, CSR, Greenwashing.

Introduction

Reputation is considered the most valuable asset of a company, and the risk of its deterioration or loss - the greatest threat to its existence and development (Porter, Kramer, 2006; Creedon 2011; Marcellis-Warin, Teodoresco 2012). Reputation is the opinion of various groups of stakeholders about an enterprise, its offer and the results of its activities, on the basis of which they make their market decisions. This opinion is built on the basis of information provided by the company to the environment, opinions of other entities about the company, but above all, on the basis of own experience or information about the experiences of other stakeholders in contacts with the company.

For many years, an important criterion through which the activity of enterprises is assessed by almost all stakeholder groups has been corporate social responsibility. The company's social commitment is noticed and appreciated by stakeholders, which translates into their market decisions: customers are more willing to buy the company's products, employees show greater commitment and are better motivated to work, business partners have greater confidence in establishing cooperation, investors are more willing to finance the company's activities (Trudel & Cotte, 2009; Haigh & Dardis, 2012; Pfau, 2008). Therefore, companies try to build their reputation as a socially responsible organization (the so-called "green" reputation), using the ideas of green marketing. It turns out, however, that many companies use green marketing tools primarily to be perceived as a socially responsible organization. So in fact, they strive to create the desired image of such an organization, which is not the same as obtaining such a reputation. The firm striving of enterprises to create the desired, "green" image often leads to simulating specific actions, deceiving and misleading customers as to the environmental performance of products and social commitment, which is referred to as greenwashing.

The aim of the article is to indicate the importance of the concept of green marketing in building the company's reputation as a socially responsible organization, indicating the negative consequences of using greenwashing practices and to propose such methods and ways of operating with the use of green marketing to make building the desired reputation more effective. Therefore, an attempt was made to answer the following research questions:

Cite this Article as: Danuta SZWAJCA "Green Marketing as a Tool for Building the Corporate Reputation as a Socially Responsible Organization – Critical Approach" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

1. What is the importance of green marketing in building the company's reputation as a socially responsible organization?

2. Do the companies using green marketing build a reputation or rather the image of a socially responsible organization?

3. What are the negative effects of greenwashing practices in the context of building a "green" corporate reputation?

4. How to use green marketing as a more effective tool for building the company's reputation as a socially responsible organization?

The following research methods were used: critical analysis of the literature, review of thematic research results and deductive inference based on the analysis of the following concepts: corporate reputation concept, stakeholder theory, creating shared value, hybrid value chain, corporate social innovation, CSR 2.0 and the ideas of sustainable development.

The importance and use of green marketing in building the company's reputation

The growing ecological awareness of societies and the increasing pressure of stakeholders result in increased requirements for enterprises as regards their social responsibility, environmental and climate protection. Therefore, all industries give up the “wave of responsibility” and the need to quickly move towards more sustainable, ethically correct practices (Laasch & Conaway, 2015). Enterprises are changing their approach to management, implementing the so-called good practices, environmental standards of the ISO 14000 series, formulate internal or industry codes of ethics, undertake environmental initiatives and pro-ecological projects carried out together with their stakeholders. Kotler (2011) notes that "more and more consumers would rather buy goods and services from companies that are concerned for the environment, which is why company managers and owners have to add the ecological vector to the administration". The approach to marketing is also changing, because its traditional concept and assumptions are criticized in the context of CSR and sustainable development (Szwajca, 2013). The approach to marketing evolves towards the concept of social marketing and Marketing 3.0, which calls for partnership and co-creation of a market offer with stakeholders, taking into account the good of the consumer and the whole society (Kotler, Kartajaya, Setiawan, 2011), as well as towards green or sustainable marketing.

Green marketing is defined as "the process of creating, communicating and delivering value to customers. in a way that makes it possible to protect or strengthen both environmental and social capital in all respects ”(Martin, Schouten, 2012, p. 10). Leitner (2010) or Belz and Peattie (2010) emphasize that green marketing should cover all activities of the company, ensuring ecological and social benefits throughout the product life cycle, from the idea to the withdrawal of the finished product from the market and its disposal

Sustainable marketing understood in this way requires the development and implementation of sustainable marketing mix tools. Belz and Peattie (2012) proposed a new "4C" composition instead of the classic "4P" marketing mix structure (Table 1).

Table 1: Traditional marketing mix versus sustainable marketing mix

Traditional marketing mix	TRANSFORMATION	Sustainable marketing mix
Product	→	**C**ustomer solution
Price	→	**C**ustomer cost
Promotion	→	**C**ommunication
Place	→	**C**onvenience

Source: Belz, Peattie, 2012.

In the presented approach, the manufactured and offered products or services are to solve specific problems of consumers, not only without generating social or environmental problems, but also serving to limit and eliminate them. Sustainable price is seen primarily as a cost source for the customer, therefore these costs must be well justified and documented. Instead of traditional promotion, based on the use of classic advertising and PR tools, communication

based on dialogue and cooperation with clients and other stakeholder groups should be introduced. Green communication is primarily intended to serve the environmental education of consumers, popularize and highlight the advantages of green products, and promote the idea of sustainable consumption.

The task of green distribution is to provide the customer with the convenience of accessing products, saving time and energy when purchasing, the possibility of disposing of the used product and / or its packaging, etc., while striving to minimize the consumption of natural, human and material resources.

Since the 1990s, international concerns and enterprises on almost all continents have been implementing green production technologies and green methods of manufacturing products throughout their entire life cycles, from design to disposal, achieving better economic results (Sarkis, 2017). The Swedish car manufacturer Volvo entered the Japanese market in 1996, promoting environmentally friendly systems for the production and operation of cars and the possibility of recycling each model. The company believes that it was mainly due to these actions that it increased its share in the Japanese car market by 17% over the next few years (Erginel. 2001) and is following a green strategy in the European, American and Australian markets. Japanese concern Sony in 1994 launched the "Greenplus Project", the aim of which was to improve the environmental performance of the company's products. As a result, by 2000, over 500 Sony products had been awarded the "Greenplus" label (Elwood, Case, 2000). A good example of a green product are Nike shoes from the Nike Considered line, made of vegetable-tanned leather without the use of toxic chromium (Sarkis, 2017).

According to many authors, the adoption and implementation of a green business strategy leads and will lead to gaining a competitive advantage in the future (Kiran, 2012; Leonidou et al., 2017). Therefore, enterprises are increasingly implementing green solutions and using green marketing tools because they want to be perceived and assessed as socially responsible organizations. The positive impact of green marketing on the product / brand image, corporate image and corporate reputation, the level of trust and loyalty of customers is confirmed by research conducted in many countries around the world (Ko, Hwang, Kim, 2012; Supeková, 2014; Kumar, Ghode, 2015; Wu, Lin , 2016; Bati, 2016; Mallek, Alipour, 2016; Widyastuti et al., 2019). Luo and Bhattaacharya (2009) suggest that the benefits to corporate social responsibility associated with marketing may also lead to the creation of so-called moral capital that protects the value of the company's shares.

The cited examples of pro-ecological orientation of enterprises and the implementation of green marketing tools as well as the results of many studies allow us to claim that green marketing is effective in building both the image and reputation of the company as a socially responsible organization. However, many companies use green marketing to build not so much a reputation, but only the image of a socially sensitive organization, that is, they want to be seen as such in the first place. Image is not the same as reputation, although these are interrelated categories.

Corporate reputation versus corporate image

Most authors believe that reputation and image are not the same concepts, although there is no full agreement as to the mutual relations between them (Fombrun, 1996; Barnett et al., 2006; Walker, 2010, Abratt & Kleyn, 2012). The indicated differences relate to the definition, nature, stability over time, mechanism and tools for creating these resources by the enterprise. The image is defined as a picture, set of impressions, ideas and associations about the company that arise in the minds of recipients. This image is the result of the accumulation of stimuli and information coming to the recipient from various sources, which are interpreted by him through the prism of his individual knowledge, beliefs and feelings. The image is not very permanent, it can be created relatively quickly by the company using appropriate Public Relations tools or suggestive advertising campaigns. On the other hand, reputation is understood as an opinion about the company and its activities, formulated by various groups of stakeholders through the prism of their interests and expectations towards the company. Reputation is the result of verifying the compliance of deeds with words, that is, the actual actions of the company with its promises and declarations. Thus, the image as an effect of various external stimuli can be artificially created in the minds of recipients, while reputation cannot. Reputation requires "hard evidence", because stakeholders assess the real effects of the company's operations. Reputation cannot be built overnight, it takes a longer time, measured in years. The foundation of reputation is the trust of stakeholders, which is not easy to gain in a short time (see: Szwajca, 2016). The differences between the image and reputation are presented in Table 2.

Table 2: Corporate image versus corporate reputation

Corporate image	Corporate reputation
Perception of the company	Evaluation of the company
It has an individual character	It has a social character
Built more on perception	Built more on experience
Mainly based on communication	Based on the identity and activities of the company
It can be artificially created	Based on verifying actions with words
Created in relatively short time	Created in relatively long time
More unstable in time	More stable in time

Source: Szwajca, 2018.

At this point, it should be noted that the image and reputation are valuable resources for the company that should support each other: a positive, reliable image, responsible for a credible message, strengthens the reputation, and a good reputation contributes to creating a favorable image (Fig. 1).

Fig. 1: Corporate image and corporate image – interaction

Source: Szwajca, 2018.

The pursuit of enterprises to build the image of an environmentally friendly and socially responsible organization leads to abuse, manipulation and misleading public opinion as to actual actions and behavior, which is called greenwashing. The term "greenwashing" was coined by renowned New York Times environmentalist and journalist Jay Westerveld, who in a 1986 essay revealed that the hotel industry falsely promotes towel reuse as part of a broader environmental strategy, when in fact it is about the economic benefits of reducing laundry (Orange and Cohen, 2010). Greenwashing emerges both at the level of corporate strategies and at the level of the marketing mix tools used, and includes various forms of deceptive communication (Lyon and Montgomery, 2015; Markham et al., 2014).

It turns out that greenwashing is a practice quite commonly used by companies. In 2008-2009, researchers from TerraChoice reviewed over 1,000 products of large American companies, presented as environmentally friendly

products. It turned out that all the tested products (except one) showed some form of greenwashing (Aji, Sutikno, 2015). Ecologists, journalists, activists and various social associations reveal many greenwashin practices (Wiech, 2019).

By applying unfair green marketing practices, enterprises are following a certain trend towards being green and are probably not fully aware of the negative consequences, taking into account the fact of growing awareness of consumers and other stakeholder groups, access to information, its quick dissemination and high probability of revealing the truth. Research carried out by the PR Cone Communication agency showed a growing distrust towards pro-ecological slogans used by companies in promotional messages. The vast majority of Americans surveyed (80%) show serious skepticism about the pro-ecological attitude and actions of enterprises subject to the principles of sustainable development (Bzdyra-Maciorowska, 2012).

The effects of greenwashing practices in the context of building a "green" reputation

The negative effects of greenwashing have been the subject of research and analysis for many years and have been identified by many researchers from different countries and continents (Krafft, Saito, 2014). These effects relate to: the company's image and reputation, brand image and capital, buyers' purchasing reactions, customer loyalty and trust and other stakeholder groups, and as a result, the company's profitability and financial results. A study by Chen and Chang (2013) among Taiwanese consumers in the electronics market revealed negative links between greenwashing and customer confidence. It turned out that there are two important factors that weaken buyer confidence: 'green confusion' and perceived 'green risk'. This is because customers feel cheated and misled, which causes them a negative feeling of disorientation and serious fear of purchasing the company's product again.

Similar conclusions can be drawn from research on "green capital" of the brand of gas stations in Turkey. Research has shown that greenwashing negatively and directly affects brand value, and what's more, it also generates 'green confusion' and 'green risk', which in turn reduce the trust of environmentally sensitive consumers in the brand (Avcilar, Demingunes, 2017). Berrone et al. (2017), after researching 325 US publicly traded companies operating in the most environmentally harmful industries, found that the pro-environmental activities undertaken by these companies help them obtain environmental legitimacy. However, when environmental indicators deteriorate and NGO control reveals mocking of the company's environmental activities, i.e. greenwashing, the company may lose its environmental legitimacy, which translates into its stock exchange quotations.

On the other hand, research conducted among consumers in India showed that they are more and more aware of the unfair use of "green marketing" tools by enterprises, which negatively affects the level of trust in brands promoted as organic, as well as undermines the green image of these brands and weakens consumer loyalty towards them (More, 2019). Similarly, Szabo and Webster (2020) proved that greenwashing can result in ethical damage: negative perception of the company's products and consumer skepticism, which in turn leads to a decrease in their confidence in the company and dissemination of unfavorable opinion to other stakeholder groups. Consequently, ethical damage adversely affects the company's profitability.

In view of the presented unfavorable consequences of greenwashing, the question arises: how can enterprises use green marketing to prevent it from being negatively perceived and exposing the company to another "green" reputation risk?

Cooperation with stakeholders as a method of more effective building of a "green" corporate reputation - discussion

It seems that one of the effective methods of building the company's reputation as a socially responsible organization with the use of "green marketing" tools is engaging stakeholders in the process of creating a market offer. According to the theory of stakeholders, enterprises are forced to take into account the interests and requirements of various groups of stakeholders, as these groups have more and more opportunities and power to influence the decisions and results of the enterprise (Rydzewska, 2016). Therefore, in the context of the stakeholder theory, it seems reasonable to cooperate with stakeholders and jointly develop a product offer. The idea of co-creating an offer with stakeholders (primarily with customers) has been propagated for several years by Prahalad and Ramaswamy (2004), suggesting the need to move from the space of creating products to the space of creating solutions to specific problems. It is about developing third-generation collaboration, which concerns joint action along the entire value chain by developing innovative green products and creating new markets (SustainAbility, 2007). Research in the UK construction sector has shown that

stakeholder engagement can be a driving force in the implementation of green business models (Abuzeinab & Arif, 2014). The authors of the research suggest that the organisation's competence to interact and cooperate with stakeholders in creating innovative, ecological offers will be the main factor changing the conditions of competition.

The proposed cooperation with stakeholders in the field of green marketing refers to the concept of the so-called social innovations based on the theory of social consent by K. Davis, as well as the concepts of creating shared value, hybrid value chain, corporate social innovation or CSR 2.0, along with such tools for generating ideas as crowdsourcing and crowdfunding (Szwajca, 2017). Social innovation involves the development and implementation of new ideas (products, services, business models) to meet social needs and create new social relationships. They are based on the ingenuity and cooperation of various entities and stakeholder groups: citizens, non-profit organizations, local communities, enterprises, public institutions (Herrera, 2015; Osburg, Schmidpeter, 2013). Stakeholders may, on the one hand, be inspiring and co-creators, and on the other hand, beneficiaries of such innovations, which will contribute to building their satisfaction and good opinion about the company. Research conducted by Padgett and Moura-Leite (2012) showed a positive relationship between reputation and corporate expenditure on innovations that generate high social benefits. It is worth adding that this approach may also contribute to reducing the risk of innovative activities of enterprises (Nawrocki, 2016).

There are examples of many companies that cooperate with stakeholders and implement socially engaged investments and social innovations. The Yara company, the world's largest producer of mineral fertilizers, has been cooperating with local authorities and governments of many African countries in the development of logistics infrastructure for years. The effects of this cooperation are: better access of African farmers to mineral fertilizers and modern cultivation methods, an increase in agricultural production efficiency, and thus - an increase in sales and revenues of farmers, and a decrease in unemployment (Driessen Hillebrand, 2013). In the 1980s, Nike established a team of specialists to improve the company's processes and products in the context of sustainable development, and companies such as GM, Wal-Mart, Coca-Cola and Clorox cooperate with social organizations for environmental protection (Martin, Schouten , 2012).

Effective cooperation with stakeholders requires their proper selection, taking into account their substantive skills, ethical qualifications, as well as willingness to cooperate. One solution to this problem seems to be encouraging stakeholders and making attempts at such cooperation. This is confirmed by, among others the results of research by Driessen and Hillebrand (2013), which showed that companies involving stakeholders in the processes of creating "green products":

- first, they have developed and apply techniques to identify relevant stakeholder groups,

- secondly, they use mechanisms to detect contentious issues and tensions between stakeholder groups with conflicting expectations,

- developed rules allowing to prioritize ecological criteria by assigning them appropriate weights.

Cooperation with appropriately selected groups of stakeholders gives a chance to build their trust and credibility in terms of the reliability of activities undertaken in the field of green marketing, and trust is the foundation of reputation. In this way, green marketing can become an effective tool for building the company's reputation as a socially responsible organization.

Conclusions

The concept of green marketing is a response to the accusations made against traditional marketing, the concept and assumptions of which are contrary to the philosophy of CSR and sustainable development. The essence of green marketing consists in striving to reduce the negative impact on the environment through the use of a green marketing mix: an environmentally friendly product, socially reasonable price, promotion of ecological products and a healthy lifestyle, low-energy distribution combined with waste disposal.
Due to the growing environmental awareness and the pressure of key stakeholder groups, enterprises strive to build their green reputation, i.e. the reputation of a socially responsible organization. As many studies show, companies successfully use green marketing tools for this purpose. However, in many cases, green marketing is mainly used to

create a green image rather than a green reputation. The image as the image of the company in the mind of the recipient can be artificially created by means of green advertising and PR, while the reputation is based on confronting the company's declarations with real facts.

Too strong striving of companies to be perceived as environmental organizations leads to greenwashing - manipulation and misleading about the harmlessness of products, environmental involvement of the company, etc. These unfair practices are exposed in a shorter or longer time, which results in very unfavorable consequences for the companies using it. Greenwashing increases the skepticism of consumers and other stakeholder groups, which reduces the popularity and effectiveness of green marketing, and moreover, generates so-called "green" risk. Companies that really care about the environment and offer ecological products, thus promoting them run the risk of a lack of credibility, accusation of fraud and deliberate misleading of the public.

In order for green marketing to be an effective tool for building the company's green reputation, a method was proposed based on developing cooperation between the company and appropriately selected groups of stakeholders in creating a green offer and implementing the so-called social innovation. It is especially about designing innovative, environmentally friendly products throughout their life cycle - from the idea to the disposal of the finished product. This solution creates an opportunity to build the credibility and trust of stakeholders, which are the foundation of reputation. The research initiated in this area allows for the formulation of such a hypothesis, the confirmation of which requires extensive research and argumentation.

Abstract

The paper describes the areas where the regional technological observatory can be useful for innovative companies that tie their development with the development of regional smart specializations. The paper presents the scope of information presented by the Regional Technology Observatories in the Silesian Province matched with the expectations of entrepreneurs representing smart specializations. The Regional Technology Observatories have been created as instruments for monitoring development strategy at the regional self-government level. The scope of gathered information may be useful for the companies sector that are one of the most important stakeholders of the implemented pro-innovative policy. Because the scope of gathered information on smart specializations within European regions is similar, the presented recommendations may be useful in different regions based on analogy even if there are no specialist observatories or other initiatives to monitor economic data within the scope of research and development, innovation and development of individual sectors.

Keywords: Observatory of Technology, Business Development, Business Strategy.

Introduction

The main role of the observatory of technology is to provide knowledge to decisionmakers about the current state of technology (Santa Soriano et al., 2018). Monitoring or observing the technology is a very important operation that allows for orienting the operations within the scope of technology first and foremost in case of companies that use them in practice. The nature of the technology makes it difficult to observe. According to Burgelman et al. (2009) technology „*is the theoretical and practical knowledge, skills and artifacts that can be used to develop product and services, as well as their production and delivery systems. Technologies can be embodied in people materials, cognitive and physical processes, plant, equipment and tools. Key elements of technology may be implicit, existing only in an embedded form (like trade secrets based on know-how) and may have a large tacit component.*" Mastering the technology by companies and knowledge on technologies used in the sector are key elements of company's knowledge management. It is due to these reasons that the companies monitor technological areas using various sources of information and specific methods and techniques. This information business entities use to formulate strategy or to make strategic decisions in the area of research and development. This area develops the resources of the organization and requires analysis of environmental analysis and economic analysis (Patz, 1986).

An important practical question emerges: What should be the role of the self-government authorities of the region in supporting the business sector? What kind of information and knowledge analysed by regional authorities is especially valuable for business? Experience of the Silesian Voivodeship and entities supporting the regional innovative policy partially answer these questions. The purpose of the paper is to present the activities Network of Regional Specialized Observatories (NRSO), information collected by the observatories and their role for business sector in innovation-based development.

Literature Review

Innovations and smart growth are at the forefront of current challenges related to regions development. The issues such as resilience, digitization and smart specialization are key determinants of the regional innovation strategies

Cite this Article as: Lilla KNOP and Sławomir OLKO "Regional Observatory of Technology as a Tool Supporting Development of Innovative Businesses in Region" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

that enable to focus on providing research and development infrastructure, financial support for innovation at companies or technology transfer resulting from cooperation with R&D entities.

Approach such as this emerged from innovative regions and environments (Camagni, 1991; Crevoisier L., 1997), hi-tech sectors (Keeble and Wilkinson, 2000), knowledge based clusters and industries (Cooke, 2002) and the phenomena of knowledge infiltration (Bottazzi and Peri, 2003). The Innovation Policy of the European Union (Derlukiewicz, 2010), results directly from the European Strategy of Development - Europe 2020 - based on smart development. The policy of smart specialisations raise political, social and scientific disputes concerning the level of public support concentration, impact on the level of regional product and unemployment rate. Category of smart specialisation (Foray and Van Ark B., 2007; Foray at al., 2009; Foray, 2009; Kardas, 2011), in particular, means that competitive edge is based on knowledge resources that allow for improvement, development and introduction of breakthrough solutions. System support of innovations within the region concerns also the sector of companies which used the innovations to support business models (Brzóska, 2014).

Smart specialization is to stimulate mutual support of technology and disciplines based on inter-sectoral relationships and dissemination of knowledge not only within the scope of the region. The strategy focuses on using current knowledge and technology to implement innovative solutions under any and all possible forms, including organizational and marketing innovations and innovations oriented at users and society. This does not imply that the regions should not create new knowledge, especially those which are at the brink of breakthrough changes. This means that smart specialization strategy sees the role of technological and non-technological innovativeness as well as applies to both hi-tech and traditional sectors. It this case, it was assumed that:

1. regions cannot do everything in science, technology and innovation and;
2. they need to promote what should make their knowledge base unique and superior to others. (Foray D. et al. 2009; OECD, 2013).

Based on the assumptions, the selection of smart specializations should be based among other things on (European Commission, 2012):

- the existence of key assets and capabilities (incl. specialised skills and labour pools) for each of the areas proposed and, if possible, an original combination of these (cross-sector; cross-cluster),
- the diversification potential of these sectors, cross-sectors or domains,
- critical mass and/or critical potential within each sector,
- the international position of the region as a local node in global value chains. Process approach in implementing regional innovation strategy consists in identifying.

Regions, especially in EU, maintain their own policy of innovative development that is a complementation of the innovative policy of the state. The literature provides relationships of region development with such issues as: knowledge management and intellectual capital. Lönnqvist and Laihonen point to four basic areas of knowledge management in the context of the region development: business intelligence, intellectual capital management and information management (Lönnqvist and Laihonen, 2013). Zhao and Ordoñez de Pablos (2011), in the theory of management, proposed placing the knowledge management at the regional level. It results from it that a region can be treated as a specific organization that implements all management functions (planning, organizing, motivating and controlling) for its stakeholders.

Components of the regional innovation system are the instruments implementing the innovative policy at the regional level that covers entities engaged in operations supporting their tools and operations. The system uses tools such as clusters, innovative grids and platforms (Cooke, 2012).

Technology used by the regional sector of business represents a very important element of an innovative development. Even though most of the technologies are of global character, there is a regional adaptation of these technologies and their development for the benefit of the companies in the region (Martinez and Rodriguez 2019).
Andersen & Andersen (2014) introduced the term Innovation System Foresight (ISF) i.e. a system that allows for predicting important changes of technological and social character, considering current level of social, technological and economical maturity of states and regions.

Implementation of smart specialization strategies necessitates its proper monitoring and evaluation. The monitoring relates to the necessity to trace implementation progress. Evaluation is assessment whether and how the strategic goals are met. First and foremost, the paper focuses on the issue of monitoring the smart specialization development. The fact that the process of monitoring the regions development is a subject that has been evolving for at least two decades is key in this case. In order to evaluate the results of the regional policy and strategy,

analyses of processes and phenomena as well as development trends are performed. Records in the monitoring system usually show a set of indicators that grows every year.

The term "indicator" has been used for the first time in 1942 by the American sociologist Dodd (1942). The methodology of creating and applying the indicators has been focused mostly on social and civil indicators and has been related to public programmes in order to improve the social situation of the selected social groups in the Unites States and United Kingdom. In Poland, the issue of indicators in public policies has been propagated since 2004, i.e. since the Polish accession to the European Union and implementing the financial programmes from the structural funds. This caused that evaluation of indicators in Poland is strongly affected by the European Commission methodology. Indicators of products, results and impact are the most common ones. When looking at the indicators as the measure of the determined objective, achieved result, it is assumed that they should consist of definition, value and unit of measure.

The purpose of the observatory of technology was based on the observatory established in the area of Key Enabling Technologies (KET): "Observatory aims to provide EU, national and regional policymakers with information on the deployment of KETs both within the EU-28 and in comparison to other world regions (East Asia and North America)" (European Commission 2015).

Regional Observatory of Technology (ROT) is the undertaking the purpose of which was to win and deliver knowledge on development of technology to the major stakeholders of regional development: regional authorities, companies established within a given region and institutions cooperating with companies. The organizational form of ROT may correspond to differentiated configuration of entities composing the regional innovation system: it may be hierarchical, heterarchical (network form), polycentric, it may also have dual nature, i.e. have some hierarchical and heterarchical features (Cooke et al. 1997). The hierarchical organization is important in case of shaping the regional development policy, in turn, heterarchy is better suited in peer-to-peer relationships of entities engaged in the innovative processes.

Analytical tools applied by the technology observatories include among other things analyses of publication bases, bibliometric analyses, analyses of patent or scientific publication bases (Carbonell et al. 2017).

According to RIS3, the system of indicators should include (European Commision 2012):

- indicators reflecting the research and innovations within the region such as the level of R&D and technological specialization, based on the existing data such as patents, publications, expenditures on R&D, HR in R&D, new products and technologies,
- economic indicators that may indicate new sectors or traditional ones with the potential for development based on research and innovations and with good perspectives such as predictable share in market, incomes, level of productivity,
- indicators related to evaluation of the level of cooperation between the R&D system specific for a given business process and the latter, showing the chances for relationships between the actors, such as number of inventions, common publications, cooperation contracts, common projects, spin-off companies, public-private partnerships, clusters, etc.

However, emphasized indicators should meet the following criteria:

- Clear – should be precise and unique,
- Relevant – adapted to the evaluation object,
- Economic – attainable with reasonable costs,
- Adequate – should suffice to evaluate the results,
- Monitorable – subject to assessment by independent experts.

Network of Regional Specialized Observatories (NRSO) – organisation and provided information

Methodology

The paper adopts the case study method, wherein the case is the undertaking of creating the Network of Regional Specialized Observatories (NRSO). In the case study the following areas were analysed: organisation of NRSO, activities undertaken by NRSO and analysed information and its value for the business sector.

Organisation of NRSO

The assumption underlying the cooperation within the NRSO is the contract specifying duties of each institution participating in the network and mutual relationships and relations between these entities (Bondaruk et al., 2016). The contract specifies tasks of the entities within the frameworks of the presented scientific and technological specializations. In particular, the network members committed themselves to search for financial support for the network operations in the form of projects.

Organizational form of NRSO such as understanding is without time limit and imposes specified duties on the partners however without specifying consequences from failure to complete the said duties. In the contract, the partners express their intent to search for financial support of the observatories operations in the form of projects without any limitations as to the scope of financial support source. Adoption of a project-based approach provides an opportunity to adapt short-term objectives specified in the project to current needs of the stakeholders in the region. Another important consequence of applying the project-based approach in NRSO is the precise determination of project products which are at the same time the effects of NRSO functioning. The products must be achieved and the partners implementing the project are liable for it. Failure to achieve the project products in case of public financial support imposes financial consequences on the partners - project-based approach enforces therefore the mechanism of coordination and verification of the observatory tasks.

There are 8 active observatories in the NRSO:

1. **The Observatory for Energy** has been established in 2013. It is created by the consortium in the following composition: Scientific and technological part „Euro-Centrum" Sp. z o.o. – leader, Agencja Rozwoju Regionalnego w Częstochowie S.A. (Regional Development Agency in Częstochowa) Operations of the observatory are based on the supporting entrepreneurs in the sectors related to energy efficiency and RES utilization. These operations are based on creating and strengthening market standing of companies by delivering technological and useful knowledge for the purposes of energy management in the production processes and within current operations. At the moment, the observatory supplies information given in the sectoral reports and technological reports to the interested entities. The reports mostly include the analyses of RES and EE technological trends, strategic recommendations, information on specific RES and EE market segment, comparative analyses (technological benchmarking), R&D work monitoring within the scope of RES and EE in the region and country. Within the competences of the Observatory the following key indicators are developed i.e. Green Energy Index, Knowledge Index and Index of Green Poviats.
2. Specialist observatory within the **Technologies for the Medicine** area, established in 2013 - consortium in the following composition: Górnośląska Agencja Przedsiębiorczości i Rozwoju Sp. z o.o. (Upper Silesian Entrepreneurship and Development Agency) – leader, Fundacja Rozwoju Kardiochirurgii im. prof. Zbigniewa Religi (Prof. Zbigniew Religa Cardiosurgery Development Fund), Instytut Techniki i Aparatury Medycznej ITAM (Institute of Medical Technology and Equipment), Silesian University of Technology. In the global economy, the industry of medical products belongs to the most profitable and the fastest developing areas. This is an industry of advanced technologies, intensively developing in highly industrialized countries with innovative economies and high national income per capita. The Silesian Province has significant intellectual and economic resources within the scope of medicine and related advanced technologies, therefore it was selected within the scope of the Regional Innovation Strategy, as one of three smart specializations of the region.
3. The specialist observatory within the area of **Information and Telecommunication Technologies**, established in 2013. Park Naukowo-Technologiczny „Technopark Gliwice" Sp. z o.o. is the chief coordinator. The main objective of the observatory is development of the technological and innovative potential of the region through building competitive edge of entities operation within the ICT sector.
4. The specialist observatory within the area of **Technologies for Aviation Industry** has been established in 2019 and it is represented by the Silesian Science and Technology Centre of Aviation Industry. Operations of the observatory are aimed at strengthening the region development through supporting the regional scientific and technological potential within aviation and related technologies. It is also an attempt to transfer the scientific and research cooperation to international level which is important for the aviation sector and sectors where the aviation technologies are applied due to their global character and dissemination of innovations. The monitored aviation technologies are positioned from the perspective of capacity of practical application in other related industry sectors.
5. The specialist observatory within the area of **Nanotechnologies and Nanomaterials** has been established in 2014 - composition of the consortium: University of Silesia in Katowice - leader, NANONET Foundation for Nano Sciences and Nanotechnologies, Non-Ferrous Metals Institute and Centre of Polymer and Carbon Materials PAN. Operations of the observatory are focused on building competitive edge of the

province through development of the technological and innovative potential of the region. Information analysed and provided by NRSO.

6. Specialist observatory within the **Technologies for Environment Protection**, established in 2013 by Central Mining Institute. This observatory has been established to answer the specific needs of the stakeholders of the Silesian Province innovation ecosystem within the scope of creating modern mechanism for monitoring the results of innovative region development within particular technological areas.
7. The specialist observatory within the area of **Materials Production and Processing** - established in 2019 - composition of the consortium: Silesian University of Technology – leader and Non-Ferrous Metals Institute. The scope of operations of this specialist observatory covers gathering information and data necessary for the regional authorities to diagnose the potential within a given technological area, monitoring and evaluating the impact of public interventions on development of the technological area, serving the function of an "animator and advisor" for companies, entities supporting development of the region. Depending on the needs, the observatory offers services in the following form: advisory and training, organization of events, meetings, workshops, seminars, study visits, etc., cooperation with national and foreign observatories.
8. The specialist observatory within the area of **Transport and Logistics** under establishment wherein the Silesian University of Technology is its chief coordinator. The results of the first works of the observatories will be the model of cooperation of companies with the cities within the scope of the last mile transport organization. Different paths of the product commercialization will be developed. Advisory services performed based on the developed model will be provided to companies performing logistic services. Companies coming to the observatory will obtain the knowledge within the scope of: options and methods of establishing cooperation with cities and knowledge on available solutions and barriers related to the last mile transport within a given city and possible organizational solutions based on the city potential.

Information analysed by observatories

From among the statistical data that might be important for the companies representing smart specializations, the following must be mentioned:

- number of enterprises operating in the sector corresponding to smart specialisation,
- production value,
- value of investment of the companies sector within the regional and sector array
- value of expenditures on R&D within the regional and sector array

This values are presented in Table 1 for the industries corresponding to material production and processing. However the regional data for these industries are not available in public statistics. According to information obtained in regional statistic office they are estimated for the regional purposes.

Table 1: Basic characteristics of material production and processing sector in Poland

Division of NACE	Description	Number of enterprises		Production value [mln EUR]	
		2010	2018	2010	2018
22	Manufacture of rubber and plastic products	8 233	9 458	12.979.7	22,790.0
23	Manufacture of other non-metallic mineral products	10 028	10 735	9,984.0	14,377,9
24	Manufacture of metals	1 047	1 427	9,447.3	14,519.9
25	Manufacture of fabricated metal products, except machinery and equipment	28 127	44 736	14,775.7	27,789.4

Source: Eurostat, 2020

The value of gross expenditures of enterprises for innovation for the region and Poland is presented in Fig. 1. The regional data for specific industries representing smart specialisation are not available in public statistics while they could be very valuable for regional business. The role of NSRO could be estimation of these date to provide current, regional data according to expectations of business sector.

Fig. 1: Gross expenditures of enterprises for innovation in the Śląskie region and in Poland 2010-2019, Source: Central Statistical Office (GUS), access: 2020

NSRO collecting the data of development of each of the regional specialisation. The list of uniform indicators for the specialist areas has been developed based on available data with division to types of indicators, according to the determined pattern:

- uniform indicators for the observatories within the scope of technological areas of reporting type,
- indicators characterizing the potential of a given technological area within annual scale,
- components of regional progress indicators.

In the tables 2, 3, 4 these information are presented for the two selected observatories: Environment protection technologies and ICT. In accordance with the assumptions of the NRSO functioning, every active observatory will prepare the data in

Table 2: Uniform indicators for the observatories within the scope of technological areas of reporting type

No	Indicator	Unit of measure	Environment protection technology		ICT	
			Year	Value	Year	Value
1	Number/type of performed services within a given technological area in favour of entrepreneurs, including SME, R&D sector entities	pcs	2014	2	2017	91
2	Number/type of reports developed in favour of entrepreneurs, including SME, R&D sector entities within a given technological area	pcs	2014	1	2017	1
3	Number / type of developed publications within a given technological area	pcs	2014	1	2017	n.d.
4	Number of companies, including SME, R&D sector entities using the services within a given technological area	pcs	2014	45	2017	n.d.
5	Number / type of organized workshops, trainings, seminars within a given technological area	pcs	2014	2	2017	10
6	Number of participants in the workshops, trainings, seminars within a given technological area	pcs	2014	53	2017	83

Conclusions

NRSO functioning as ROT was subordinated to practical objective of shaping innovative policy of a region and assisting in making decisions. Based on analysis of NRSO activities including information analysed by the observatories, the following conclusions may be drawn:

1. The information analysed by NSRO are used mainly for the realisation of regional innovation policy: monitoring if implementing smart specialization, and adjusting the public support of innovation.
2. The Silesian Voivodeship is one of few regions in the EU that performs systematic observation of technological areas important for the development of a region in the form of ROT. The region also develops the Technology Development Programme (TDP) as a separate strategic document orienting the technological development of the region, representing the complementation of the Regional Innovation Strategy and support for smart specializations of the region. Such approach should be applied especially within the industrialized areas, whose smart specializations are strongly related to technology.
3. Analytical methods used by NRSO are relatively straightforward, experts in their disciplines used the generally available technological reports as well as scientific and patent databases. The main problems of analysing these kind of information are related to the limited possibilities of extracting regional data.

4. The observatories face a challenge of lack of specific regional data. According to the presented reports sometimes it is caused by unclear definition (e.g. key competence center, living lab). In other cases, the reason is missing regional data in official statistics.
5. Despite the participation of the companies sector in the observatory works, the interest of companies in the observatory works results is moderate. This is also related to a significant weakness of the region within the scope of innovation - low level of financial support for R&D from private sources. Representatives of entrepreneurs did not show any interest in prospective studies - presenting possible scenarios of technology development, evaluating them as not reliable enough in the context of rapid changes in the environment or too general, despite the sectorial nature of the reports of each of the specialist observatories.
6. Considering the presented activities of NRSO and providing information, note that this is a kind of a regional information system available for many regional stakeholders including business sector. Utility and success of this undertaking depends on engagement of users of the delivered knowledge on technologies, therefore NRSO operations should be continuously adapted to expectations of the business users.

Acknowledgment

The data analysis were financed by the regional project “A Network of Regional Specialist Observatories in the Process of Entrepreneurial Discovery in Śląskie Voivodeship” WND-RPSL.01.03.00-24-06A2/16-004, theoretical research and publication of the paper was financed from statutory work conducted by Department of Management and Logistics, Faculty of Organization and Management, Silesian University of Technology.

Perception of Consumer Generations on Influencers' Posts in Social Media

Maria-Alexandra CALINOIU

University of Craiova, Craiova, Romania
ale.calinoiu@gmail.com

Abstract
The purpose of this article is to analyse the perception consumer generations have on influencers' posts on various Social Media platforms such as blogs, YouTube, Instagram and Facebook. The research methodology will consist in interpreting the results of a questionnaire applied to a number of 324 respondents regarding the impact of notoriety, trust, authenticity of expertise and creativity of influencers' posts on the decision to purchase a brand. The conclusion of the research is that brands are able to exponentially increase the visibility of their products and services by appealing to the popularity influencers enjoy, thus reaching the target audience much faster and more efficiently.

Keywords: consumer generations, Social Media platforms, influencer marketing, eWOM.

Introduction

Social Media gives users the opportunity to express their opinions about various products and services as a result of the consumption experience in order to share them with others. This has led to an increased desire for brands to maintain a positive image and generate favourable customer experiences, minimizing negative reviews that can easily spread among potential customers.

Many brands use Social Influencers not to sell a product, but rather to expose consumers to the brand as well as its story (Alderton, 2014). Moreover, this type of marketing is effective for brands that want to strengthen their market position and reach a younger demographic (Steimer, 2017).

Given the fact that new generations of consumers are increasingly moving away from traditional media, their interests are moving online and clustering around trusted influencers who share their experiences in Social Media (Soltysinska, 2017). According to an official finding report by ANA (The Association of National Advertisers), 86% of brands use Influencer Marketing in their promotion strategies. Out of these, only 0.6% consider content generated by influencers to be irrelevant, while 53% of brands consider it very valuable.

The Collaboration between Brands and Social Influencers

Uzunoğlu and Kip (2014) argue that it is vital for brands to work with influencers to build a trustworthy and authentic presence in the online communities. And also that brands benefit from buzz-power from influencers that translate into increased visibility through exposure in the influencer's community.

Moreover, Chau and Xu (2012) argue that social networks are the most important marketing channels because of the strong competition that electronic Word-of-Mouth (eWOM) generates. Influencers increase the efficiency of these channels. According to Li et al. (2015), identifying effective influencers in social networks is essential both for reducing promotional spending and for creating business opportunities in eWOM marketing.

Choosing the right influencers has a significant impact on the brand image as influencers can effectively manage reviews, amplifying the value of positive ones and diminishing the effect of negative ratings (Li and Du, 2014). According to a study by Jansen, 50% of product and service evaluations carried out on Social Media are positive, while 33% are negative, with the remaining 17% inconclusive (Jansen et al., 2009). The same study revealed that a negative rating causes a brand to lose 30 customers (Jansen et al., 2009). Although the partnership between a brand

Cite this Article as: Maria-Alexandra CALINOIU "Perception of Consumer Generations on Influencers' Posts in Social Media" Proceedings of the 36th International Business Information Management Association (IBIMA), ISBN: 978-0-9998551-5-7, 4-5 November 2020, Granada, Spain.

and an influencer is a win-win situation as both parties benefit from this collaboration (Uzunoğlu and Kip, 2014), an influencer may lose credibility by collaborating with a brand whose products and services have questionable quality (Uzunoğlu and Kip, 2014). Moreover, collaboration with influencers must become a strategic alliance based on common values and objectives so that the influencer does not contradict its own values when passing on the brand's message (Booth and Matic, 2011).

Fig. 1.1. Influencer Marketing Impact on Consumer Behaviour

Source: by author

Direct sales have proven for decades that people prefer recommendations and trust relationships more than marketing messages (Alderton, 2014). Influencers' posts are messages close to WOM recommendations and have a real impact on their loyal audience (Soltysinska, 2017).

Studies have shown that e-WOM influences both consumer behaviour (Chen, Wang and Xie, 2011) and brand sales (Chevalier and Kicka, 2006). In the online environment, recommendations have a positive impact on consumers' views on a particular product or service and therefore encourage a purchase (Cheung, et al., 2009). Teenagers have become much more aware of the products and services they purchase and consume. Therefore, before making a purchase decision, they check customer reviews several times and are not based solely on the product advertising (Sa'ait, Kanyan and Nazrin, 2016). Studies have shown that 90% of online shoppers consult the opinions of other consumers before purchasing anything (Channeladvisor, 2011), and 70% of consumers trust e-WOM (Nielsen, 2012). The more opinions consumers have on a product or service, the greater the influence e-WOM has on purchasing decisions. It is a question when brands pay for reviews and thus obtain less authentic consumer experiences with which they associate. In excess, sponsored e-WOM leads to a decrease in brand confidence. (Sa'ait, Kanyan and Nazrin, 2016). The more relevant an influencer's opinion becomes to readers, the more they gain confidence in that influencer's recommendations, thus positively impacting the e-WOM which acquires a greater degree of authenticity (Colliander and Erlandsson, 2015).

Research Objectives

In order to observe the impact that both influencers and brands have on consumer behaviour, we conducted an online survey based on a questionnaire (Annex 1) applied to a sample of 324 respondents, which was the support for the quantitative research. The survey was conducted between May 7 through 14, 2020, and the data analysis was made in Microsoft Office Excel. The objectives of the research are the following:

- identifying the degree of visibility that an influencer gives a brand
- identifying the degree of trust in the products and services of some brands recommended by influencers
- identifying the degree of authenticity of the experiences that influencers have with brand products and services
- identifying the level of expertise of niche influencers who recommend brand products and services
- identifying the degree of creativity of influencers' brand posts
- the impact of notoriety on the decision to purchase a brand
- the impact of trust in influencers' posts on the decision to purchase a brand
- the impact of authenticity in influencers' posts on the decision to purchase a brand
- the impact of niche influencers' expertise on the decision to purchase a brand
- the impact of creativity in influencers' posts on the decision to purchase a brand
- identifying the channel with the greatest influence on consumers
- breakdown of influences on generations of consumers

Research hypotheses and proposed model

The proposed model identifies purchase and satisfaction as determinants of brand loyalty. The purchase mediates the relationship between satisfaction and loyalty. In return, the purchase of a brand is influenced by five variables: notoriety, trust, authenticity, expertise, creativity. The proposed model is illustrated in Figure 2.1.

Figure 2.1: Research model

Source: made by the author

The proposed model is consistent with the theories regarding the impact of Influencer Marketing on consumer behaviour (Keller and Kotler, 2016). We started the research from the idea that consumer exposure to online brands will have a similar effect in real life and vice versa, because consumers create a virtual representation of it through the use of the Internet (Schau and Gilly, 2003). This idea leads to the reasoning that the influence that is realized online affects the intention to purchase in real life, as well as the perception on products and services. Notoriety describes the degree of brand visibility offered by influencers by passing on the brand message to the community. Thus, the first hypothesis can be laid down:

H1: Positive notoriety influences the purchase.

The recommendations that a brand receives from someone else are more credible than what the brand says about itself. A third party, whether an influencer or a regular consumer, can reinforce the brand's claims or contradict them through a negative user experience. This outlines the second hypothesis

H2: Positive trust influences the purchase.

Brands have changed their communication strategy and no longer focus on selling, but on creating stories and experiences, shaping experiential marketing. The connecting experiences are made through blogs, vlogs, YouTube, digital publications and podcasts and thus create more and more content that is not aimed at direct sales. Experiences provide the authenticity that consumers expect and develop the desired connection of brands. (Sloof, 2018) The third hypothesis is laid down:

H3: Positive authenticity influences purchase.

Influencers play a very important role and, at the same time, their recognition grows rapidly due to the fact that they provide information synthesized in various forms and functionalities (Akritidis et al., 2011). The main factors that define the consumer's tendency to be influenced by a certain factor largely concern the correct information, at the right time, in the right place and from the right person (Wu, 2012). Thus, the fourth hypothesis is laid down:

H4: Positive expertise influences the purchase.

Influencers spread information through various Social Media channels, such as blogs and social networks, they share stories and images, they tell their experiences, express their opinions on many topics, services and products, and are a portrayal of the very important phenomenon of influence (Alsulaiman et al., 2015; Alhidari et al., 2015). The fifth hypothesis is laid down:

H5: Positive creativity influences the purchase.

Profile of the Respondents

The profile of the respondents in terms of characteristics is presented in Table 2.1 below. They were selected in their own network of acquaintances, being invited to answer the research questionnaire through Social Media channels.

Table 2.1: Profile of quantitative research respondents

Variable	Classification of the variable	Frequency	Total share
Gender	Female	116	35.8%
	Male	208	64.2%
Environment	Urban	254	78.4%
	Rural	70	21.6%
Age	under 25 years old	158	48.8%
	26-42 years old	104	32.1%
	43-53 years old	33	10.2%
	over 54 years old	29	8.9%

Source: made by the author

Research results and hypothesis validation

In the sample structure, the people who are best represented are those under 25 years old - Generation Z (48.8%), closely followed by people aged between 26 and 42 years - Generation Z (32.1%), and respectively the people from the urban environment (78.4%). In terms of gender, males are best represented (64.2%). According to the built methodology, they provided answers regarding their consumption behaviour.
We analysed the factors that influence the purchase of a brand in terms of statements evaluated on a Likert scale from 1 (total disagreement) to 5 (total agreement). Research has shown that the social responsibility of brands has the greatest impact on the purchase of a brand (3.92), followed by the notoriety instilled by influencers (3.82). The lowest result was obtained by the creativity of online posts (2.93).

We comparatively analysed consumers' perception of the factors influencing the purchasing decision (notoriety, trust, authenticity, expertise, creativity) that refer to influencer posts made in order to promote the products and services of some brands they work with, depending on communication channels (blog, YouTube, Instagram, Facebook). The results are given in Table 2.2. According to the research, the biggest influence on the decision to purchase a brand promoted by influencers lays with the blog posts (3.471), followed by YouTube (3.314) and Instagram (3.30). Facebook posts have the least impact due to the degradation of content quality as a following the increase in the number of fake posts. This has led to a decrease in trust in the posts that appeared on Facebook, which had a significant impact on the activity on the other platforms. Influencers focused their attention on blogs, YouTube channels and Instagram accounts, a fact confirmed by the results of the study.

Table 2.2: Analysis of the impact of influencers' posts from the main Social Media platforms on the decision to purchase a brand

	Notoriety	Trust	Authenticity	Expertise	Creativity	Total
Blog	3.74	3.24	3.22	3.20	2.956	**3.471**
YouTube	3.89	3.23	3.31	3.19	2.953	**3.314**
Instagram	3.89	3.25	3.25	3.21	2.953	**3.30**
Facebook	3.77	3.16	3.16	3.10	2.89	**3.20**

Source: made by the author

At the same time, we analysed the impact of the five indicators (notoriety, trust, authenticity, expertise, creativity) on the purchasing decision separately and comparatively for each generation of consumers (Generation Z, Generation Y, Generation X, Baby Boomer).

According to the research results, presented in Table 2.3., Influencers have created brand awareness (notoriety) for brands as follows:

- on the blog, the highest level of notoriety belongs to Generation X (3.78), and the lowest to Generation Z (3.70)
- on YouTube, the highest level of notoriety is found in Generation Z (4.05), and the lowest in Baby Boomer
- on Instagram, the highest level of notoriety is also obtained by Generation Z (4.03), and the lowest by Baby Boomer (3.51)
- on Facebook, the highest level of notoriety belongs to Generation Y (3.96), and the lowest to Generation Z (3.65)

Table 2.3: Perception of the different consumer generations on influencers' posts in Social Media

		Generation Z	Generation Y	Generation Z	Baby Boomer
Notoriety	**Blog**	3.70	3.77	3.78	3.75
	YouTube	4.05	3.76	3.81	3.55
	Instagram	4.03	3.89	3.56	3.51
	Facebook	3.65	3.96	3.81	3.72
Trust	**Blog**	3.02	3.25	3.68	3.89
	YouTube	3.15	3.19	3.59	3.44
	Instagram	3.12	3.19	3.5	3.62
	Facebook	2.84	3.23	3.65	3.44
Authenticity	**Blog**	3.08	3.15	3.56	3.96
	YouTube	3.25	3.31	3.40	3.55
	Instagram	3.13	3.22	3.65	3.62
	Facebook	2.94	3.28	3.65	3.34
Expertise	**Blog**	3.01	3.24	3.40	4
	YouTube	3.10	3.17	3.62	3.34
	Instagram	3.10	3.24	3.56	3.48
	Facebook	2.91	3.16	3.56	3.44
Creativity	**Blog**	2.66	3.99	3.5	3.89
	YouTube	2.81	2.87	3.46	3.48
	Instagram	2.84	2.86	3.37	3.44
	Facebook	2.60	2.98	3.40	3.65

Source: made by the author

These results indicate which channel influencers should focus on in order to take the brand message forward to each generation of consumers, as follows:

- Generation Z is present most on YouTube and Instagram and less on blog and Facebook
- Generation Y is more present on Facebook and less on YouTube
- Generation Z is present most on YouTube and Instagram and less on blog and Facebook
- The Baby Boomer Generation reads blogs and has a weak presence on Instagram

Therefore, the posts of influencers who take the message of brands to consumers will have greater visibility if they are posted on the blog for Baby Boomer, on YouTube for Generations Z and X, on Instagram for Generation Z, on Facebook for Generations Y and X.

After seeing which are the Social Media channels that offer the highest visibility to influencers' posts that promote brands, we analysed the level of consumer confidence in these posts, the results being shown in Table 2.3. Thus:

- on the blog, the highest level of trust in posts comes from the Baby Boomer Generation (3.89) and the lowest from Generation Z (3.02)
- on YouTube, the highest level of trust in posts comes from the Generation X (3.59) and the lowest from Generation Z (3.15)
- on Instagram, the highest level of trust in posts comes from the Baby Boomer Generation (3.62) and the lowest from Generation Z (3.12)
- on Facebook, the highest level of trust in posts comes from the Generation X (3.65), and the lowest from Generation Z (2.84)

These results indicate that Generation Z is the most reluctant to trust the posts of influencers, but is also the generation that follows influencers the most. Generations X and Baby Boomer have the highest level of trust in influencer promotional posts as they believe that if a person appears in public to talk about a product and service, then what they are saying is true, without particularly double-checking the information in other sources.

Regarding the consumers' perception of the authenticity of the posts, shown in Table 2.3, it can be stated that:

- on the blog, the highest level of authenticity indicated by influencer posts is perceived by the Baby Boomer Generation (3.96) and the lowest by Generation Z (3.08)
- on YouTube, the highest level of authenticity indicated by influencer posts is perceived by the Baby Boomer Generation (3.55) and the lowest by Generation Z (3.25)
- on Instagram, the highest level of authenticity indicated by influencer posts is perceived by the Baby Boomer Generation (3.65) and the lowest by Generation Z (3.13)
- on Facebook, the highest level of authenticity indicated by influencer posts is perceived by Generation X (3.65) and the lowest by Generation Z (2.94)

Generation Z retains the same reluctance to the authenticity of influencers' posts, regardless of the Social Media channel on which they are posted. Generations X and Baby Boomer are the ones who deem authentic to the greatest extent these brand promotion posts made by influencers.

We also analysed consumers' perception about the level of expertise they consider influencers who promote brand products and services have, in order to see which generation considers influencers to be experts in the field they work in. The results of the research are shown in Table 2.3. Therefore, we have:

- on the blog, the level of expertise of influencers perceived by consumers has the highest level for Baby Boomer Generation (4) and the lowest for Generation Z (3.01)
- on YouTube, the level of influencers' expertise perceived by the consumers was the highest for Generation X (3.62) and the lowest for Generation Z (3.10)
- on Instagram, the level of influencers' expertise perceived by the consumers was the highest for Generation X (3.56) and the lowest for Generation Z (3.10)
- On Facebook, the level of influencers' expertise perceived by the consumers was the highest for Generation X (3.56) and the lowest for Generation Z (2.91)

The Baby Boomer Generation perceives bloggers as experts in their niche, while Generation Z sees influencers as normal people, just like them, but with an incredible online voice. Generation Z consumers understand that influencers appear online to present their consumer opinion, their personal experiences with brands' products and services, not as brand specialists that have an informed opinion.

The perception on the creativity of the posts has the lowest level of the five factors and the research results are also presented in Table 2.3. Thus:

- blog posts are perceived as creative mostly by Generation Y (3.99) and the least by Generation Z (2.66)
- YouTube posts are perceived as creative mostly by Baby Boomer Generation (3.48) and the least by Generation Z (2.81)
- Instagram posts are perceived as creative mostly by Generation Baby Boomer (3.44) and the least by Generation Z (2.84)
- Facebook posts are perceived as creative mostly by Generation Y (3.65) and the least by Generation Z (2.60)

To the most part, the consumers from the Baby Boomer Generation consider influencers' posts to be creative, while Generation Z is the least impressed by the creativity of influencers' posts on blogs, YouTube, Instagram and Facebook. One explanation for this would be the migration of Generation Z to TikTok.

According to the statistics presented in the Digital Marketing Report, made by iSense Solution, in Romania there are 176,335 TikTok users, most of them young people up to 25 years old, i.e. from Generations Z and Alpha (children born after 2010) - 113,715. On TikTok, the youngsters from Generation Z are very creative, they always strive to bring something new, to impress and stand out.

So, the biggest challenge for both brands and influencers is to go back to being authentic and human in communication, as this is the only way they can get the attention of the Generation Z.

Conclusions

Given that messages and opinions spread quickly on Social Media, the brand is able to exponentially increase the visibility of its products and services, appealing to the popularity enjoyed by influencers, thus reaching the target audience much faster and more efficiently. In return, the influencer enjoys the brand's reputation for the purpose of improving their contact list and level of fame. Influencer Marketing has become a powerful advertising tool that has a much greater impact compared to other forms of promotional communication. This phenomenon is constantly expanding, and its importance is confirmed by a growing number of studies, observations and reports.

Abstract

Trust in organisation creates a climate conducive to information exchange, sharing ideas, and therefore innovation. It can also be a factor that will be crucial for implementing innovations.
The article presents the results of the empirical research related to the determinants of innovation. The authors concentrates on one of the most important determinants, which is 'trust'. Both practitioners and theoreticians deal with the problems of managing innovation, seeking its determinants which can emerge by minimising barriers to the creation and implementation of innovations. Trust is a decisive factor for a company's innovativeness and performance. On the other hand, innovation can be practised as well as learned. The purpose of this article is to show how to formulate and implement corporate values to promote the development of innovations and their effective use in the development of the long-term value of an organisation. The study was conducted on 50 organisations operating in Poland were examined (they were different in terms of size, industry and ownership structure).

Keywords: Trust, Innovation, Management

Introduction

Both practitioners and theoreticians deal with the problems of managing innovation, seeking its determinants which can emerge by minimising barriers to the creation and implementation of innovations. They focus primarily on the formulation and implementation of various determinants of innovation (e.g. trust), to promote the development of innovations and their effective use in the development of the long-term value of an organisation.

Trust has always been one of the most important determinants of innovation (Bleicher ,1991; Sink, et al. 1995; Lane, 1998; Wilson and Kennedy, 1999; Hacker and Willard, 2002; Sztompka, 2005; Grudzewski, et al. 2009, Walecka-Jankowska, 2014). Innovations, as a the central capability for all organisations interested in maximizing the opportunities for success, is related to the process of creating and sharing knowledge (Dobni 2010; Jaruzelski and Dehoff 2010; Walecka-Jankowska 2011; Gobble 2012). The result of these actions is related to the presence or lack of trust in the organization. Trust will be important at almost every stage of the innovation process, creating an atmosphere for the creativity of employees.

The aim of the article is to indicate what type of trust is conducive to the development of innovations and their effective use in the development of enterprise value.

Trust - Theoretical Approach

The role of trust in society and organization is more and more often emphasized by many authors, including: Griffin (1996), Zand (1972), Gambetta (1988), Bleicher (1991), Misztal (1996), Fukuyama (1995 and 1997) , Doney, Cannon and Mullen (1998), Handy (1995), Robbins (1998), Keen (1999), Zimniewicz (2000), Zeffane, Connell (2001), Bednarczyk (2001), Grudzewski and Hejduk (2004), Watson (2005), Sztompka (2007); Bianchi and Brockner (2012); Bews (2012); Colquitt, LePine, and Piccolo (2012). An unequivocal definition of the concept is, however, difficult due to the fact that it is an old concept, moreover, of an interdisciplinary nature - the issue of trust is dealt with by sociologists, psychologists, economists and philosophers. As a consequence, there are many definitions in the literature - some of them are presented in Table 1.

Tab 1: Trust definitions

Authors	Definition
Psychology and sociology	
Griffin, 1967	Relying on a person's behavior to achieve a desired but uncertain goal in a risky situation.
Cook, Wall, 1980	The degree to which a person is willing to attribute good intentions to others, to believe their words and actions.
Barney, Hansen, 1995	"(...) mutual belief that neither party will take advantage of the other's vulnerability".
Management	
Zand, 1972	Actions: sensitizing, aimed at someone who is not under control, when the punishment is borne by one party, when it is abusing the other party's sensitivity, is greater than the benefit received by the party using that sensitivity.
Gambetta, 1988	The probability that the person with whom we cooperate will perform appropriately entrusted tasks or at least their actions will not be harmful enough to require breaking the cooperation.
McAllister, 1995	The level to which a person is confident and wants to act on the words, actions and decisions of others.
Fukuyama, 1995	Expecting honest, mutual and repeatable behavior based on standards commonly accepted by some members of the community.
Blomqvist, 1997	The belief that the other party will do what it has committed to.
Böhme, 1998	Ontological trust is based on the fact that the perception of each person is based on the thought patterns developed by him (as part of communication or during gaining experience), helping to organize and interpret the world around him. Ontological trust occurs when you can rely on your thought patterns - to give you sufficient orientation in reality. Institutional trust, in turn, refers to the belief in the functioning of certain institutions, which include the legal system, social order (e.g. the applicable hierarchy) or the laws of nature (e.g. sunrise and sunset).
Doney, Cannon, Mullen, 1998	Willingness to rely on the other party and act when the other party's actions are very important.
Burgol, (2006)	"Trust is something that has been created in an organization for people and by people, and is based on a certain level of predictability (the effects of and consequences)" (p. 22).
Calnan, Rowe, (2006)	“Trust is not an individual attribute or mental state, but it is the result of interpersonal behavior and shared identity. These behaviors result from institutional rules, laws, customs" (pp. 349-358).
Chen, Barnes, (2007)	"Trust is perceived utility, perceived security, perceived privacy, perceived good reputation and the desire to personalize the offer as important prerequisites for initial online trust" (pp. 21-36).
Grudzewski, Hejduk, Wańtuchowicz, 2009	"Trust is the belief on the basis of which Unit A in a specific situation, he accepts the dependence of unit B (person, object, organization), having a sense of relative safety, even though negative consequences are possible”.
Bugdol, 2010	"Is convinced that the actions taken lead to the achievement of the set goals and gaining benefits by all stakeholders).
Organizational behaviours	

Zaheer, McEvily, Perrone, 1998	Expecting the participant to fulfill their obligations, their actions to be predictable, and to act and negotiate fairly, even if they behave opportunistically.
Robbins, 1998	It is integrity, competence, consistency, loyalty and openness. It should be noted, however, that integrity and competence are decisive in whether a person is trusted or not.
Szeloch, 2001	It distinguishes the technical and moral dimension of trust - the technical dimension of trust consists of competences, skills and abilities, and the moral dimension consists of two elements: good will (willingness to do good) and righteousness of character (honesty, justice, truthfulness and faithfulness to one's conscience).
Weber, Deepak, Murnighan, 2005	"Trust is the foundation of social interactions, a valuable, valuable resource located in organizational and interpersonal relations"
Sankowska, 2011	"Trust is the readiness to become sensitive to the actions of the other party based on the assessment of its credibility in a situation of interdependence and risk" (p. 34)
Source: own work based on Walecka-Jankowska, K. (2001), Wpływ zarządzania wiedzą na innowacyjność przedsiębiorstw, PHD dissertation, Politechnika Wrocławska; Wydział Informatyki i Zarządzania. Grudzewski, W.M., et al. (2009), Zarządzanie zaufaniem w przedsiębiorstwie, Wolters Kluwer, Kraków.	

The key issues in defining trust are: kindness (concern and motivation to act in the interests of the other party - is the opposite of opportunistic actions) (Holmes, 1991), honesty (making contracts in good faith, telling the truth, keeping promises) (Bromiley and Cummings, 1995) , competences (actions and / or skills necessary to do what is needed (Barber, 1983), predictability (regarding desired and undesirable actions that are consistent enough to be predicted (Gabarro, 1978; Grudzewski, et al. 2009). Thus, to sum up, trust is associated with the existence of certain expectations about the future, rooted in the social order in which the trustee functions. Trust arises in conditions of acceptance of the other party's behavior and develops in conditions of voluntary and unforced cooperation. At the same time, it exists in conditions of uncertainty and risk. and the trustee has no control over the results based on trust (Grudzewski, et al 2009; Hosmer 1995; Whitener et al. 1998). Importantly - it is a positive concept by nature, moreover, by some it is referred to as fragile (Sztompka, 2007), therefore susceptible to changes, especially under the influence of negative factors, while others consider them permanent, because it grows with progress (Zand, 1972).

Types of trust

Trust may result from various premises and takes different forms in different interpersonal relationships. That is why there are many typologies of organizational trust related to various sources of its origin and the type / durability of the dominant relations, on which this trust is based. Table 2 presents selected typologies of trust.

Tab. 2 Type of trust

Lewicki i Bunker, 1995	
Based on deterrent	based on calculation and logical behavior of partners. Punishment is regarded as a negative factor, a reward as a positive and predictable effect. Based on reward for fulfilling obligations, not fear of punishment.
Knowledge based	based on the prediction of behavior resulting from experiences gained during cooperation in the past.
Based on identification	based on empathy, care, shared values of partners. Focus on shared tasks, not individual needs.
Barney i Hansen, 1994	
Weak	the belief that the other party will not take advantage of their helplessness; lack of control and contract; it occurs when there is no possibility of opportunistic action.
Average	it is based on the control mechanisms: reputation, a contract protecting against opportunistic actions.
Strong	principled, results from the assimilation of the norms and rules governing the activities of business partners and is dependent on control mechanisms.
Sako, 1992	

Contractual	results from the ability to abide by contractual arrangements - common norms, honesty, keeping promises, common understanding of principles and standards.
Competence	it results from the tendency to act in accordance with the promises made.
Good will	it results from commitment and mutual benefits arising from it, it exists when there is an agreement on the principles of fairness (it is considered conducive to cooperation and taking into account the achievement of satisfaction).
Harrison, Cummings i Chervany, 1995	
Personality	based on the structure of the human personality. It is focused on the innate and acquired personality traits of individuals within the organization. The ability to empathize with others, sensitivity, responsibility and emotional restraint are examples of traits that show a high personal tendency to trust.
Calculative	based on a simple calculation of the costs and benefits of a given relationship. The domination of this dimension proves a good motivational system, organizational identity, and the involvement of individuals in organizational matters.
Institutional	based on formal regulations. It consists in shaping a sense of security on the basis of formal safeguards.
Perceptual	is the process of perceiving the behavior of other people. This dimension refers to the cognitive characteristics of individuals and describes trust in terms of observing mutual behavior, reactions, and ways of proceeding.
Cumulative - knowledge-based	this is the most durable category of trust, but requires quite a long initiation time. It develops on the basis of gained and accumulated experience.

In this study the classification of Lewicki and Bunker (1995) was taken, due to the explicit and direct relationship of trust types indicated by the authors with the sources that build this trust (and therefore relationships dominant in the organization) and the strength/durability of the impact of these relationships on general organizational trust.

Organizational trust based on calculation is rather weak, because it based on concerning transactional relations prevailing in the organization and estimating the risk of decision-making. Hence, this type of trust is associated with "weak trust" (Barney and Hansen, 1994) and contractual trust (Sankowska 2015) or deterrence-based trust (Rousseau, et al., 1998).

Organizational trust based on calculation is rather weak, it is based on the least durable type of relationship between people, because it comes from concerning transactional relations prevailing in the organization and estimating the risk of decision-making. Barney and Hansen (1994) called this type of trust – weak, Sankowska (2015) contractual trust, Rousseau et al. (1998) deterrence-based trust.

Organizational trust based on knowledge (competence-based trust) known as a semi-strong, results from a relationship based on the long-term experience of the organization's participants (Sankowska 2015) and results, in turn, from the previously gathered positive exchange experiences. This type of trust can grows due to a common interaction history that allows to develop generalized expectations for the partner and predict the behavior.

The trust of goodwill (called relational trust) is the strongest one, because it grows on long-term relationships based on values shared by the organization’s participants. As Sankowska (2015) noticed it refers to relationships based on identification. Emotions that arise from the more frequent and longer interactions between the parties of exchange causes that the partners rely on each other, care for each other and focus on common values and needs.

It is possible that the indicated three types of organizational trust can and even exist in the organization at the same time, and general organizational trust is a kind of resultant of relationships and motivations occurring in the organization. Lewicki and Bunkier suggest that trust is evolutionary. Therefore, usually at the beginning of a relationship there is trust based on calculation. At this point, the parties to the transaction most often calculate the possible benefits and losses that may result from the relationship. Most often, to be able to talk about a relationship and develop it, the benefits must be higher than the costs. This stage is followed by an increase in experience resulting from cooperation with a partner. Therefore, we can speak of trust based on knowledge, as the parties are able to predict the reactions of the other partner. The last stage is to understand your partner's needs and care for their welfare. Therefore, one can speak of a trust based on identification. Partners "develop common goals, values and identity, and

there is often a tendency to give up short-term goals for the sake of cooperation." In connection with the above, we can talk about the evolution of trust over time, which depends on the nature and history of cooperation" (Sankowska, 2015).

Trust and innovation
